Abstract

This thesis examines the current method of forecasting foreign currency exchange rates for the annual US Air Force budget. Using 5 methods against the status quo of a center-weighted average, the paper evaluates the absolute percent error (APE) over three time periods extending from Fiscal Year (FY) 1979 to FY 2014. The results strongly indicate that four of the alternative methods outperform the status quo over the shorter time period, and one method for all three time periods. Furthermore, a non-parametric comparison of the median APE demonstrates statistical similarities between the four methods over the short term, and allows for the Air Force to choose which method to exercise for future forecasting. Overall, the paper recommends using the settlement price of the average option contract in October to decrease the median APE by 3.475% and avoiding a $36 million opportunity cost.

Acknowledgments

I would like to express my gratitude to my family for their patience and understanding for all the nights spent working on this thesis. I would also like to convey my sincere appreciation to my faculty advisor, Lt Col Jonathan Ritschel, for his guidance and support throughout the course of this thesis effort. The insight and experience was certainly appreciated. I would, also, like to thank my sponsor, Lt Col Andrew Wallen, the Senior Economist for the Secretary of the Air Force – Financial Management for both the support and latitude provided to me in this endeavor. Finally, I am in debt to Dr. White for teaching me about robust statistical analysis and the application of those methods to this thesis.

FORECASTING FOREGIN CURRENCY EXCHANGE RATES FOR AIR FORCE BUDGETING

I. Introduction

The Department of Defense (DoD) obligates roughly $5 billion every year in 9 different foreign currencies[1] (Office of the Undersecretary of Defense (Comptroller), 2014). Foreign currency is necessary to pay for the daily operations, maintenance, construction and personnel costs of oversees bases and operations. As part of the federal budget process, the DoD must annually estimate the amount of foreign currency needed to fund these daily activities. Simply estimating $5 billion every year does not reflect realistic requirements. The Air Force (AF) is therefore seeking improvement in its foreign currency exchange rate forecasting methodology, which is the focus of this thesis. This chapter outlines the background of the DoD budget process and how the foreign currency exchange rate integrates into that process. It then defines the problem statement, research objective and focus, investigative questions, and assumptions. The chapter ends with a brief discussion on the methodology applied in the thesis.

Background

The DoD submits an annual budget to Congress to fund the investment and operation activities of the United States military. These activities represent approximately 18% of annual federal government outlays (or over half of discretionary spending (Office of Management and Budget, 2014)). For fiscal year 2013, the requested total obligation authority is $620 billion (Office of the Undersecretary of Defense (Comptroller), 2012).

[1] The currencies are Denmark's Krone, the European Union's Euro, Iceland's Krona, Japan's Yen, Norway's Krone, Singapore's Dollar, South Korea's Won, Turkey's Lira, and the United Kingdom's Pound.

As part of this budget submission, the DoD provides an estimate of required funding needed for expenses paid in foreign currencies. A specific account for absorbing foreign currency variability is also included and represents an opportunity cost to the DoD. Recent financial reports show an opportunity cost of $1.1 billion in 2013 and $1.4 billion in 2012 (Office of the Undersecretary of Defense (Comptroller), 2013). Over the course of 2013, the DoD's foreign exchange rate forecasts averaged a 9.61% difference from the actual average exchange rate. This gives a $105.7 million opportunity. Thus, small improvement can have significant impacts. For example, by deriving a new foreign currency estimating methodology that results in a narrowing of the difference by just 1% to 8.61%, the DoD can free an additional $10.6 million of budgetary authority.

Prior to 2005, the DoD formulated the budget's foreign exchange rates by selecting the most favorable rate observed in the months preceding the annual budget submission (Government Accountability Office, 2005). The most favorable rate provided the highest amount of foreign currency per dollar, and did not provide a realistic assessment of funding requirements. A Government Accountability Office (GAO) investigation in 2005 guided the DoD exchange rate forecasting process into a more rigorous statistical methodology excluding subjective judgment in picking the most favorable exchange rate. Since the 2005 report, the DoD has used a centered weighted average technique to estimating, resulting in more accurate forecasting in choosing exchange rates.

An austere budget environment (e.g. sequestration) forces the DoD to evaluate the opportunity cost of the current forecasting method. New research and data may provide a more precise formula for minimizing the difference between predicted and actual rates.

A shadow, though, is cast over the entire field by a seminal paper in 1983 (Meese & Rogoff, 1983). An examination of empirical exchange rate models of the 1970s did not fit out-of-sample data any better than a Random Walk model, and subsequent papers in the 1990's and 2000's seem to carry this claim (Moosa, 2013). The debate is not over, though, as some researchers find opportunities in measuring success through different avenues than out-of-sample testing (Engel, Mark, & West, 2007).

Problem Statement

This thesis aims to develop an unbiased forecast methodology, free from the estimator's subjective judgments, with the least variance between predicted currency exchange rates and actual currency exchange rates.

Research Objectives/Questions/Hypotheses

The following objectives guide this thesis. The thesis will perform a general survey of applicable forecasting methodologies, remove any methodologies based on unrealistic assumptions or an analyst's bias, and compare the methodologies by their variance of predicted opposed to actual exchange rates given a sample data set. In order to not repeat the mistakes identified in the GAO report (Government Accountability Office, 2005), special attention is given to minimizing subjective influence or biases in the methodologies.

The purpose of the research is to answer three questions:

- Which is the best method for the Air Force to apply in formulating a budget rate of foreign exchange in terms of variance?

- Which is the best method for the Air Force to apply in formulating a budget rate of foreign exchange in terms of simplicity?
- What is the probability that a given method will budget too little and require funds from the Foreign Currency Fluctuation account?

Research Focus

The focus of this research is on current forecast estimating methodology. The thesis reviews variables used in forecasting, assumptions in forecasting, and how to measure the variance between predicted and actual exchange rates. The forecasting period is from fiscal year (FY) 1979 to FY2014 divided into three separate time frames based on the available methods (FY79-FY12, FY91-FY12, and FY06-FY14).

Methodology

The thesis used a statistics based approach to compare the projected exchange rates to the actual exchange rate. The statistics based approach focuses mainly on variance and the measure of the margin of error between projected and actual exchange rates. The different methodologies derived from the literature forecasted a budgeted exchange rate and was compared to the actual exchange rate as reported in either the FRB H.10 average monthly exchange rate for the longer time period, or the USD(C) adjusting rates for the more recent time period.

Assumptions/Limitations

The foremost assumption in the thesis is that past behavior influences future behavior. In theory, an exchange rate can range from zero to infinity; however, the day-to-day exchange rates do not vary by such wide scales. Furthermore, while the exchange rates are discrete and positive, the percent change from day-to-day is continuous, can be positive or negative, and may have a bell-curve distribution around a mean of zero. Continuous data and a bell-curve distribution lead to assuming the change in exchange rates, as a percentage, is normally distributed. Another assumption is the varying exchange rates within a day. The thesis simplifies the intraday variability by assuming one exchange rate for the day, as given by the Federal Reserve Foreign Exchange Rate – H.10 data.

The nature of forecasting and the DoD budget process guide limitations to this thesis. Forecasting can be notoriously difficult due to unforeseen circumstances, rare events, and small disturbances with oversized impacts (think of the waves from a stone dropped into a pond). These difficulties are compounded by limitations in data. More than one rate exists for exchanging currencies depending on the location, time, and bank. The thesis, therefore, limits itself to the Federal Reserve Foreign Exchange Rate – H.10. Process limitations arise in how the DoD budgets for the foreign currency fluctuation account. The budget contains only one rate per currency, while the actual exchange rate varies according to the market. The thesis limits the exchange rate to a daily rate as reported in the Federal Reserve Foreign Exchange Rate – H.10.

Implications

Given the average error in 2013, the size of the opportunity is $105.7 million. While finding a perfect forecast model is implausible, a 1% increase in accuracy could allow for more realistic budgets. Furthermore, the GAO investigated and found past methodologies lacking in scientific rigor or too reliant on the analyst's subjectivity (Government Accountability Office, 2005). This thesis adds to the robustness of the DoD's forecasting process. Lastly, the successful narrowing of variance between a projected and actual exchange rate may allow for opportunities to effectively use limited resources in an era of declining budgets.

Summary

This chapter outlined the background of the DoD budget for foreign currency exchange. While not a significant portion of the overall DoD budget, the magnitude of foreign currency expenses and estimating represent an area to investigate with clear impact on the budget. After defining the problem statement, research objective and focus, investigative questions, methodology, limitations, and assumptions, the chapter ended with a brief discussion on the implications of the research to include the size of the opportunity, proper governance and robustness of DoD budgets, and the more efficient use of limited resources in an era of declining budgets.

The remaining sections of this thesis explore the topic in greater detail. After reviewing basic DoD budget processes, Chapter Two reviews the literature of private firm foreign currency mitigation techniques, forecasting, economic forecasting, and foreign currency exchange forecasting. Chapter Three explains the specific procedure in comparing the different methodologies and the data compiled for analysis. Results are given in chapter four giving way to a conclusion in chapter five. The conclusion synthesizes the accomplished work and recommends a course of action for the Air Force.

II. Literature Review

While precisely forecasting future exchange rates is unattainable, understanding the federal budget process, forecasting techniques and previous exchange rate research mitigates the magnitude of error in forecasting the budgeted exchange rate. The following section explains the federal budget process along with the DoD's foreign currency role in the budget process. Private, international firms must also confront exchange rate volatility. A review of private firm mitigating actions against foreign currency fluctuation provides insight into options for the DoD. The section then gives a framework of basic forecasting. Next, economic forecasting is defined before exploring current research on foreign currency exchange rate forecasting in business and the DoD. The chapter ends with a review of the main points of the federal budget process, forecasting, economic forecasting, and the DoD's efforts at forecasting foreign currency exchange rates.

The Federal Budget Process

The federal government receives tariffs, taxes, fees, and other collections throughout the fiscal year (1 October – 30 September). The executive branch obtains most of the collections for the federal government (e.g. the IRS is in the executive branch) while the legislative branch, Congress, defines the amount and activities to receive funding. The executive branch must formally request the funding and authority to use the collections from Congress through the budget process. The term "budget" is defined as the President's Budget. It is the financial plan for prioritizing and allocating resources due every February to Congress and accounts for all government agency requirements for the next fiscal year (Office of Management and Budget, 2013). Policy guides the budget as policy dictates requirements for funding.

Figure 1 presents a representative decision tree of choosing a policy and its associated budget (B_i) with the uncertainty of requesting enough or too little funding. Ex ante, the executive branch provides a budget estimate according to the current policy (e.g. in ex ante the DoD forecasts the foreign currency exchange rate). Ex post is after the uncertainty of the true budget requirement is known. The sum of the probability of budgeting enough (P) and budgeting too little (1-P) is 1. The liquidation of the budget (L_i) provides the basis from which to judge whether the budget is enough ($B_i \geq L_i$). In terms of public finance, a recoup is when the executive branch asked for too much funding while a payout requires addition funding from Congress or a transfer from other appropriations. With respect to foreign currency, the goal is to minimize B_i-L_i and L_i-B_i.

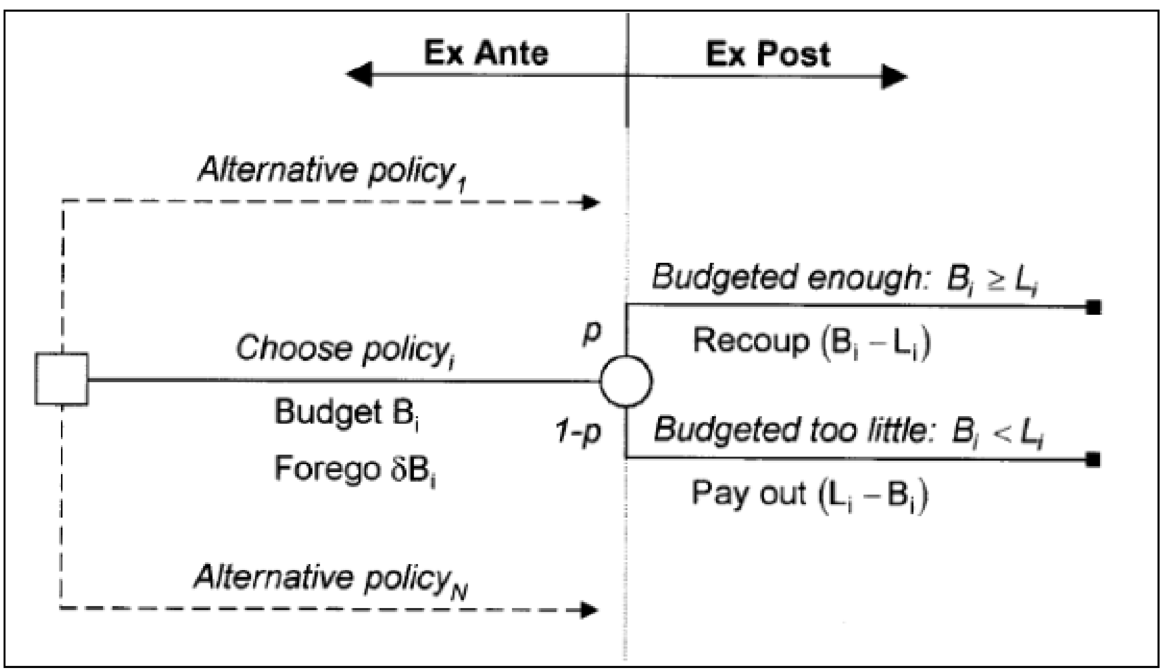

Figure 1 Decision Tree for Choosing a Budget (Groshek and Felli, 2000)

The entire Federal budget process encompasses three main phases: formulation, congressional deliberation, and execution (liquidation) (Office of Management and Budget, 2013). Foreign currency exchange rates affect the formulation and execution phases. DoD analysts forecast foreign currency exchange rates in the months preceding the budget submission during the formulation phase. Along with the other forecasted defense requirements, the DoD incorporates the forecasted exchange rates into a Budget Estimate Submission (BES). The Office of Management and Budget (OMB) integrates the BES along with the other federal agency budget estimates (e.g. the Department of Justice (DoJ) and the Department of Energy (DoE)). Budget estimates primarily focus on the budget year but also include the 9 years following the budget year (outyears) (Office of Management and Budget, 2013). Figure 2 represents the budget formulation in chronological order from the federal agency budget submission to the President's Budget.

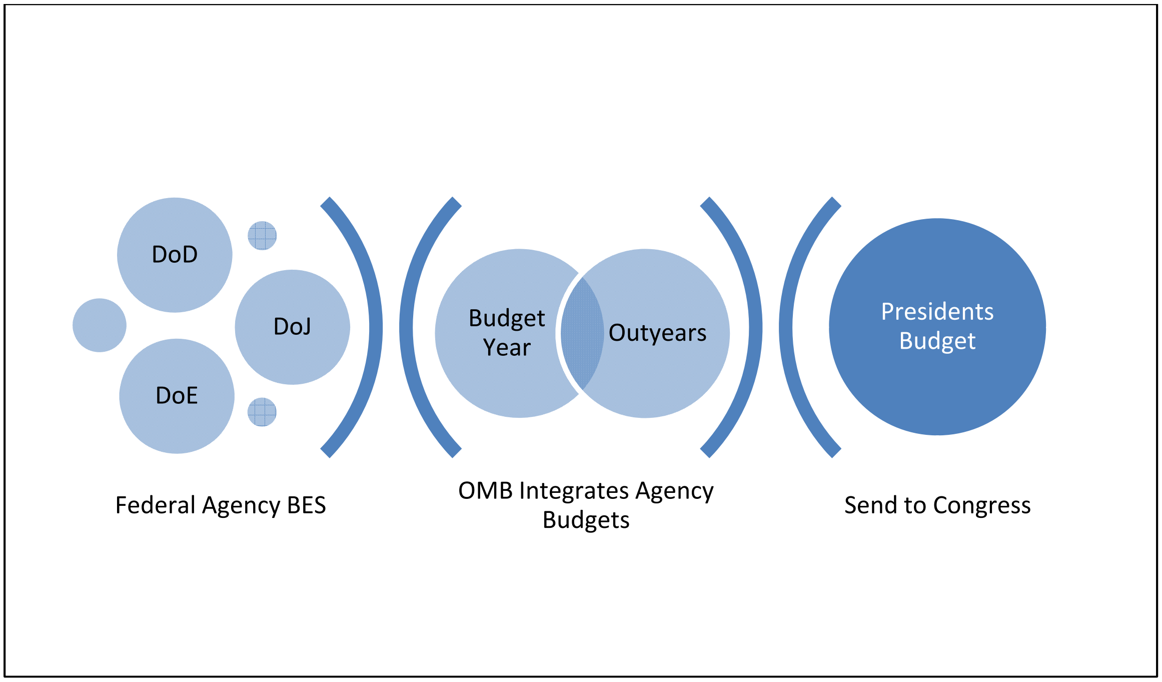

Figure 2 Budget Formulation Process

Congressional deliberation begins after receiving the President's Budget on the first Monday in February (Office of Management and Budget, 2013). The House of Representatives and the Senate deliberate separately on budget proposals. Each branch's appropriation committee reviews the BES's and calls for hearings from the federal agencies. The method of forecasting foreign currency plays an important role at this juncture, since previous inaccurate forecasts cast doubt about the cost of requirements in the budget estimate. The committees call conferences to adjudicate difference in the House and Senate committee recommendations before passing the authorization and appropriation bills. The authorization bill gives legal justification to obligate the federal government for sanctioned programs while the appropriations bill supplies funding to execute those programs (The Judge Advocate General's Legal Center and School, 2014). The President then signs the bills into law.

The execution phase follows the fiscal year beginning on 1 October and ending on 30 September. The forecasted exchange rates, then, are almost one year old by the time the fiscal year begins. During execution, each military department records foreign currency obligations at the budgeted rate. DoD's accounting office, Defense Finance and Accounting Service (DFAS), collects each military department's foreign currency obligations and compares the US dollar equivalent amount using the budgeted rate and the actual rate. The difference between the actual US dollar amount obligated and the budgeted dollar amount is the accrued variance (Department of Defense, 2011). DFAS then projects the variance to the end of the fiscal year (30 September) to analyze any significant variance for the remainder of the execution phase. Funding is transferred from the DoD's foreign currency fluctuation allotment to the military department (i.e.

Army, Navy, AF) by DFAS should the monthly report show a negative balance. With less variance, the DoD can lower the amount of funding required for the foreign currency fluctuation allotment. Better forecasting techniques helps the DoD lower the variance, and hence lowering opportunity cost by requiring less funding in a holding account.

Private Firm Foreign Exchange Rate Exposure Mitigation

The federal budget process neither flows flawlessly from one step to the next, nor is the objectives of all the stakeholders the same. Investing public dollars rests on analysis that is not solely based on monetary standards. Some examples of non-monetary standards include the benefits of sidewalk beautification projects or avoiding conflict through deterrence. Private firms, in contrast, normally quantify their investments in terms of present worth or the rate of return (Eschenbach, 2010). Table 1 highlights differences between public and private sectors. A closer review of private sector methods provides additional insights for DoD foreign currency forecasting.

Table 1 Differences in Investments Public and Private Sectors (Eschenbach, 2011)

Factor	Public Sector	Private Sector
Data	Benefits must be 1. Quantified and 2. Equated to money	Most benefits are monetary
Probability	Rare events often crucial (1 chance in 100 to 1 in a billion)	1 chance in 10 often the limit
Objectives	Multiple	Maximize present worth or rate of return
Stakeholders' Perspectives	Often conflicting	All want successful firm
Interest Rate	Complicated by nonmonetary benefits	Derived as an opportunity cost or from cost of borrowing

Private firms face the same exposure to foreign currency fluctuations as the DoD but they have more options to mitigate the risk of an unfavorable rate. Globalization and open markets enables private firms to seek new markets, raw materials, production centers, warehousing, and other supply chain functions in various countries and currencies. Dispersing supply chain functions across countries increases the risk of unfavorable exchange rate changes through transaction and operation exposure (Bodnar, 2014). Increasing forecasting accuracy is also an option when firms cannot mitigate risk through transaction or operation exposures.

Transaction exposure is the exchange rate risk a contract possesses over a well-defined and relatively short time horizon. Firms mitigate the exposure through the use of forward contracts, future contracts, money market hedge, and options (Bodnar, 2014). Forward contracts and future contracts operate in a similar manner; a firm enters an agreement that specifies a price and date at which it can buy a fixed amount of foreign currency. Futures contracts differ in that they are exchange traded requiring initial collateral. Money market hedges use a forward contract to determine the present value of the foreign currency obligation in the home country currency to reduce exchange risk. Lastly, currency options provide the owner the right to buy a currency at a specific quantity, price, and date for an upfront fee.

Operations exposure is the exchange rate fluctuation impact on a firm's business model. While transaction exposure concerns contract instruments, operations exposure focuses on marketing, product pricing, supply chains, and production (Bodnar, 2014). A firm can choose which market to sell in depending on the exchange rate as well as adjust pricing and promotional strategies to offset short term exchange rate fluctuations. For longer term exchange rate fluctuations, a firm may choose to diversify sources of inputs (i.e. the supply chain) in order to manage costs. Locating plants and other production resources in various countries also allows flexibility in choosing to manufacture product in low cost areas. The mix of production at those locations can then change according to currency fluctuations as needed.

Private firms can choose from a plethora of options; most of the options available to private firms do not apply to the DoD. Currency options and the use of derivatives are prohibited by law (Groshek and Felli, 2000). Appropriations must be obligated in the year of execution for current requirements in order to satisfy the bona fide needs rule (The Judge Advocate General's Legal Center and School, 2014). This precludes the DoD from purchasing options contract during budget formulation. The DoD may use forward contracts because the DoD does not obligate funding until the time of purchase. Furthermore, stakeholders outside of the DoD control the ability to locate military bases. National priorities, international alliances, and strategic importance outweigh the cost efficiency of locating military bases. Congress, the President, and the State Department influence these decisions alongside DoD recommendations. The lack of available exchange rate mitigation options directs the DoD to employ exchange rate forecasts.

Forecasting

One must understand the elements of forecasting in order to help lower variance between the budgeted exchange rate and the actual exchange rate. In general, forecasting is notoriously complex. A survey on forecasting research uncovered 139 principles in 16 categories (Armstrong, 2001). Forecasting techniques can be subdivided into three categories as shown in Table 2. Forecasting foreign currency exchange rates focus on quantitative methods. Quantitative forecasting requires numerical information about historical data that one can assume will continue a pattern into the future (Makridakis et al., 1998).

Table 2 Categories of Forecasting Methods and Examples of Their Application (Makridakis et al. , 1998)

Forecasting Method	*Explanation* and Example
Quantitative	*Sufficient quantitative data exists* Time Series: continuation of historical patterns Explanatory: Understanding the effects of independent variables
Qualitative	*Little or no quantitative information is available, but sufficient qualitative knowledge exists* Predicting the speed of telecommunications are the year 2036
Unpredictable	*Little or no information is available* Predicting the effects of interplanetary travel

Generally, the forecasting task can be divided into five areas: formulating the problem, collecting data, selecting methodology, evaluating methodology, and using the forecast.

Formulating a problem requires understanding the need for a forecast and the involvement of responsible parties. A forecast's necessity derives from the effect the forecast will have on a decision; one should not forecast if the result will not change a decision. Responsible parties ultimately control the decision and must be updated with forecasting results to guide the decision making process.

An understanding of the problem at the beginning directs the type of data required for analysis. Theory guides the search for explanatory variables and may uncover analogous studies. Data, though, must be unbiased and should come from sources without a vested interest in the forecast's outcome. Other sources of error can come from the procedures used to collect the data as well as measurement error from the instruments (for foreign currency an example of measurement error using only one exchange rate per day when the rate really floats throughout the trading period). After collecting the data, a formal process removes defects (i.e. erroneous observations) and transforms the data into a useful medium of analysis. Transforming data may be as simple as transcribing paperwork into a digital format or more complex like converting rates into a logarithmic function. Another adjustment prevalent in economics is the seasonality at the time of collection (e.g. seasonally adjusted unemployment figures). Analysts should adjust data according to empirical evidence of seasonality to reduce error in the data (Makridakis et al., 1998).

The type of data collected and purpose of the forecast guide methodology selection. At this point in forecasting, understanding the problem should have led to hypothesized causal relationships. The possible causal relationships inform the analyst of the data required and appropriate methodology for the investigation. The chosen method, or methods, ability to influence the decision at hand must also be considered and communicated to the decision maker. Generally, the use of a simple method is preferred unless prior research identified a more accurate complex method (Allen and Fildes, 2001). Quantitative methods are also generally preferred as they reduce the bias in analysis. If the problem has high uncertainty and questionable data, a qualitative judgmental method may be applied (such as expert opinion or surveys). Incorporating both quantitative and judgmental methods can further assist in weighing data according to importance or selecting quantitative methods. Finally, combining more than one method integrates information and reduces the risk of bias from using a particular method.

After method selection, an evaluation reviews the risks and uncertainty within the process. The analyst should test the assumptions of each method to confirm the validity of the method to the data and the problem. An independent observer should review the methodology and agree with its logic. If using more than one method, the analyst should compare the results of each method to measure the error between each method. Different scales of measurement as well as outliers affect variability in the results of one method as opposed to the other.

Using forecasts is the final step. After completing the previous steps, the analyst should present findings in a format tailored to the decision maker. Assumptions, data, and methods must be clearly presented to reduce the appearance of bias and give confidence in the forecast. Using the forecast on a regular basis allows the analyst to learn how to improve the forecast. Assimilating the improvements, an analyst can improve the forecast and reduce variability.

Economic Forecasting

What works in an experimental setting (holding all other variables constant beyond the independent variables) can produce failures when applied to real world situations (Meese and Rogoff, 1983). While it is known as the "dismal science," economics gives insights into the allocation of limited resources such as time and money. Forecasting, then, is a natural fit in economics as firms want to maximize the use of their limited resources.

Economists began using forecasting as the combination of statistical analysis and economic theory (Allen and Fildes, 2001). The main principle is to use a simple model to describe the relationship between dependent variables and a relatively small set of independent variables. The favored test regarding the usefulness of a simple model is whether the model can predict relatively accurate results with out-of-sample data (data not used in formulating the model). Testing with out-of-sample data may not give the "true" model, since any simplified model derived from a data set is a misspecification of the data. Estimating the causal independent variables induces prediction error, even with a data set created with known variables and estimated parameters (Gilbert, 1995). Another test is not how well the model predicts the dependent variable but in predicting when the dependent variable will change from growth to decline or decline to growth (Engel et al., 2007). With that said the standard remains out-of-sample validity of the model's predictions since this thesis is interested in predicting a budget rate and not the timing of foreign currency exchange rate increases or decreases in value against the US dollar.

Economists generally use a regression model to predict the dependent variable (Allen and Fildes, 2001). The use of Vector Auto Regression (VAR) and Error Correcting Models (ECM) are prominent in economics. VAR uses economic theory to narrow the number of independent variables required for predicting a dependent variable. VAR then measures the interdependencies of the independent variables to the dependent variables across a time series (a sequence of data points in temporal order). ECM ascertains a dependent variable's equilibrium value and estimates the rate at which the dependent variable returns to equilibrium through the influence of independent variables. The equilibrium can be a value or the rate at which the dependent variable changes (a vector). Both models assume constancy of exogenous variables throughout the time series and are limited by the data provided in formulating the model (in-sample data). These two models contain subsets for particular areas within economics. The focus of this research is for foreign currency exchange rate forecasting and will focus on models pertaining to that subset.

Foreign Currency Exchange Rate Forecasting

The Meese and Rogoff paper casts a shadow over the ability to predict exchange rates as tested against out-of-sample data. They found the Random Walk model (the dependent variable is a function of the last observation plus an error term) performs no worse than the univariate time series models, unconstrained VAR, or candidate structural models in forecasting real exchange rates (Meese and Rogoff, 1983). The paper states the last known observation is just as likely a predictor of future values as using other independent variables. Their conclusion demonstrated the impracticality of using independent variables based on money supply, demand, and commodity prices to predict exchange rates. The findings from 1983 still hold true as forecasts based on ex ante (before the exchange rate is set) expected changes perform poorly (Evans and Lyons, 2005). Some have suggested the use of the root mean square error (RMSE) to measure forecasting accuracy is incorrect, but measuring by time-varying coefficients with the same data do not over turn Meese and Rogoff's conclusion (Moosa and Burns, 2014).

Judging forecast methodology through other means than the actual value against predicted value leads to different conclusions about the effectiveness of exchange rate forecast models. Moosa and Burns demonstrate that a few models outperform the Random Walk when measuring forecast accuracy in terms of rate direction and in terms of profitability (Moosa and Burns, 2014). Engel, Mark, and West emphasize the Random Walk benchmark is improper as models should have low predictive power of this type

(Engel et al., 2007). They further state models incorporating news about macroeconomic fundamentals (for example GDP growth) may well account for observed exchange rate volatility. Lastly, the authors use expected present values from survey forecasts and demonstrate an increase of out-of-sample forecasting power through panel estimation and long-horizon forecasts. New forecasting methods also increase the accuracy of modeling. The short-horizon predictive ability, using Bayesian model averaging, shows large gains over the Random Walk benchmark (Corte et al., 2008). Artificial neural networks (self-learning algorithms trained on historical data) show robust exchange rate predictions in midst of outliers (Majhi et al., 2012). The results of the above research lead to the possibility of positive results compared to the Meese and Rogoff original study.

Auction theory provides another method of forecasting exchange rates. The international exchange market for currencies acts as an auction, and the future options on currencies may give insight into forecasting the exchange rate. If there are many traders for the currency, the option market can aggregate each trader's estimated price on the underlying asset (Psendorfer and Swinkels, 2000). The option price then acts as a signal of the market's approximation for the currency's future exchange rate. If the options price mirrors the actual exchange rate well enough, it may be possible to use the options price as the budgeted rate in the DoD budget.

Foreign Currency Exchange Rate Forecasting in the DoD

In fiscal year 1979, Congress authorized an appropriation for the DoD to establish a centrally managed allotment (CMA) to alleviate the adverse effect of significant currency fluctuations in authorized operations and maintenance (O&M) and military personnel appropriations (Department of Defense, 2011). The Foreign Currency Fluctuations, Defense (FCF, D) account provided the control structure to account for all transfers of net gains and losses incurred throughout the execution year. In fiscal year 1987, Congress authorized an additional appropriation, Foreign Currency Fluctuations, Construction, Defense (FCF, C, D), for the family housing and military construction appropriations. Prior to the FCF, D and FCF, C, D, the DoD could not use the additional budget authority from previous high estimates to cover the cost of current deficits. Current deficits would require transferring funding from other programs or requesting additional funds from Congress.

In 1998, Gerald M. Groshek and James C Felli of the Naval Postgraduate School examined two methods of reducing risk in the DoD to foreign currency fluctuations against the status quo (Groshek and Felli, 2000). The authors applied forward foreign exchange contracts and currency options against the naïve based approach (the status quo) from 1985 to 1998. Forward foreign exchange contracts allow the DoD to determine the required budgeted amount by applying forward rates to the estimated foreign amounts. The authors utilized Air Force O&M commitments as the budgeted amount in US dollars and Eurocurrency interest rates as the forward rates at the time of budget formulation. Under the currency options approach, the authors considered call options with an at-the-money forward strike prices. The naïve based approach simply picked an observed foreign exchange rate at some point in the budget formulation as the budgeted rate. Using the above methods, the DoD could expect a cost reduction of 3.5% of current outlays with forward contracts and 6.4% reduction using options with a 2.9% upper bound on option premiums (the premium is the cost of buying an option) over the naïve approach. The authors recommend the forward contracts since the option contracts require authorization from Congress.

Fiscal law prohibits the use of authorized funding in time periods other than the stated period in the appropriation (The Judge Advocate General's Legal Center and School, 2014). Operations and maintenance (O&M) funding is available for one year only; the government can only incur obligations against the O&M appropriation from 1 October to 30 September of the year of appropriation. To use forward rates, the US Treasury must authorize the use of a forward contract as stated in volume 5 of the Financial Management Regulations (Department of Defense, 2011). The treasury would need to have a forward pricing rate agreement across fiscal years between the US government and the foreign government or private firm for the disbursement to be made at the rate determined by the forward rate method.

The GAO investigated the DoD's foreign currency forecasting methodology in 2005 (Government Accountability Office, 2005). Despite Groshek and Felli's findings, the DoD still used the naïve based approach by using an observed rate from the Wall Street Journal in the budget process. In 2005, the DoD changed methodologies to a statistical based approach after considering the method of forecasting applied in other federal agencies, a commercial company to forecast, and various statistical methods. The statistical method, center-weighted-average, allowed universal replication without subjective judgment (Secretary of the Air Force - Financial Management Directorate of Economics and Business Management, 2010). Based on historical and current data, the chosen statistical method weighted the five year average exchange rate with the exchange rate 12 months prior. Weights range from 0 to 1 with a weight of 0 implying a budgeted rate equal to the rate 12 months previous. Excel's Solver optimizes the weights by minimizing the sum of squared errors (SSE) between forecasted and actual rates over the previous 60 months. By weighing each rate equally at the start, the process creates a forecast for each month over the previous 60 months and calculates the SSE. Solver then adjusts the weight and recalculates the SSE over the previous 60 months. The process is repeated until Solver discovers the minimum SSE. Lastly, the DoD reviews the forecasts for long term trends in developing the five year average (i.e. the Kuwaiti Dinar's pegging to a basket of currencies in May, 2007). The GAO approved of the center-weighted-average approach as it, "Provides a straightforward statistical calculation of historical data that can be easily replicated with no hidden assumptions and is not dependent on subjective judgment (Government Accountability Office, 2005)."

Another paper researched a future exchange rates predictor for the DoD in 2013 (Freund and O'Neal, 2013). The authors compared the center-weighted-average approach to five different models: moving average, prior year average, trend-lines, extending current rates, and a multivariate model. The moving average, prior year average and trend line incorporated historical exchange rates from 1, 3, 5, and 10 years in the past while extending the current rate used the recent 12 month average. The multivariate model incorporated historical exchange rate with economic factors to include historic gross domestic product (GDP), consumer price index (CPI), unemployment rates, and economically active population rates. Applying multiple regressions to account for covariance and statistical significance, the authors created a model for each currency exchange rate from the economic factors. The researchers compared all five models to the center-weighted-average by the mean squared error (MSE) between the forecasted and actual exchange rates from 1999 to 2012. Of the five models, the one year prior year average produced the minimal MSE when used across all currencies. Each currency, though, possessed a best specific model (i.e. the three year trend line had the lowest MSE for the Euro and Denmark Kroner while the five year 10 year prior year average was best for the South Korean Won). The paper recommended using the one year prior year average for formulating the fiscal year 2015 budgeted rate.

Summary

This research aims to improve the DoD budgeting process for foreign exchange rates. Budget processes, timelines, and decision authority differ from standard business firm models, but the need for accurately forecasting future requirements remains. Fiscal law precludes the DoD from many of the strategies available for private firms to mitigate exposure to foreign currency fluctuations. Forecasting, although complicated, follows five basic steps: formulating the problem, collecting data, selecting methodology, evaluating methodology, and using the forecast. Economic forecasting is a subset of forecasting that has traditionally used theory to define independent variables capable of predicting dependent variables and measures the success by out-of-sample variance. For exchange rates, the literature revealed the forecasting potential of theoretical independent variables is no better than using a Random Walk model. Meese and Rogoff's conclusion has had lasting effects throughout the decades. Some researchers have chosen to frame the problem in a new light and use new statistical methods to forecast exchange rates. A few have shown promise over the short term using artificial neural networks, shortening the time frame for a forecast, or using a aggregation of surveys and future expectations.

Others still claim the Random Walk benchmark is improper as the models do explain some variability. From the above research foundation, a few chosen methodologies will be tested for use in the DoD environment. The DoD specific research offers a starting point from which to judge new methodologies.

III. Methodology

Chapter 3 seeks the optimum method to forecast foreign exchange rates for the DoD budget. The chapter begins by defining the data sources and the suitability of the data to predicting exchange rates for the DoD. The chapter then explains the six different methods (including status quo) before describing how those methodologies will be compared. A summary of the chapter briefly reviews the material covered in this chapter.

Data Sources

There are five sources of field data for this thesis: the Federal Reserve Foreign Exchange Rate – H.10, the Global Insight forecasts, the Chicago Mercantile Exchange (CME) as taken through the website Quandl, the adjusting rates of exchange from the USD, Comptroller, and the long term interest rates as reported by the Organization for Economic Co-operation and Development (OECD). The Federal Reserve Foreign Exchange Rate – H.10 is a weekly report providing the exchange rates in foreign currency units per U.S. dollar for each day of the previous week (Board of Governors of the Federal Reserve System, 2015). Table 3 is a sample of the report taken from the Federal Reserve Board's Economic Research & Data website. Because the Federal Reserve produces the report on a weekly basis, the data were combined into one spreadsheet. The Federal Reserve data are pertinent to the research, as the rates represent the spot rate used at the time of disbursement of funds from the DFAS.

ND = No data for this date.

For more information on exchange rate indexes for the U.S. dollar, see "Indexes of the Foreign Exchange Value of the Dollar," Federal Reserve Bulletin, 91:1 (Winter 2005), pp. 1-8 (http://www.federalreserve.gov/pubs/bulletin/2005/winter05_index.pdf). Weights for the broad index can be found at http://www.federalreserve.gov/releases/H10/Weights; weights for the major currencies index and the other important trading partners (OITP) index are derived from the broad index weights. The most recent annual revision of the currency weights and dollar indexes took effect with the May 2010 release of this report. The source for exchange rates not listed in the table above but used in the calculation of the broad and OITP indexes is Bloomberg L.P.

* U.S. dollars per currency unit.

The second set of data was produced by a private company, IHS Global Insight (IHS Inc, 2015). The DoD uses the company's materials price forecasts in developing cost estimates for procurement or operations and support (e.g. shipbuilding) (Horowitz et al., 2012). This company also provides an analysis service of how world economic events, trends, and developments affect businesses and countries to include forecasts of foreign exchange rates. Using past forecasts, this research compared the actual to predicted exchange rates from the company. Forecasts from the company, though, do not provide insight into the company's methodology, which may not be sufficient for a GAO inquiry. Table 4 is an example of the 2004 fourth quarter forecast for the Japanese Yen per US dollar by quarter (highlighted) and annual forecast in Table 5.

The Quandl data contains daily futures prices on currencies from the CME. Table 6 gives an example of data containing the open, high, low, and settle prices for the contract as well as the volume of contracts traded and the bids amount of contracts available from the previous day. The futures contract prices differ according to time and contract expiration day. In order to create a historical futures series, the contracts must be combined into a continuous futures contract by combining. Combining the individual futures contracts (or 'rolling' the contracts) can follow different rules depending on the analysis. Economic forecasting uses the "first day of month" and "calendar-weighted rolling" rules. The "first day of month" roll method combines futures on the first day of the contract delivery month or on the contract end date, whichever is sooner (Quandl, 2015). The "calendar-weighted rolling" is a price adjustment to negate the discontinuities in contract prices of the successive underlying futures contracts. The method allows for transitioning from one contract to the next over 5 days where the first contract is weighed 100% on day 1 and 0% on day 5. The opposite is true for the second contract. The percent shifts by 20% each day between the first and second contract. Using the "first day of month" and "calendar-weighted rolling rules" provides a continuous data set for analysis. This research used the average of daily settlement prices to forecast exchange rates.

Adjusting exchange rates are published monthly on the USD Comptroller website (Office of the Undersecretary of Defense (Comptroller), 2014). The publication lists the budgeted rate for the fiscal year in question along with the monthly foreign currency rate as the adjusting rate. The budgeted rate column provides the status quo estimate and the adjusting rate column provides the actual rates for the study period between FY06 to

FY14. The adjusting rate serves as the actual rate in calculating the error for all the methodologies in the FY06-FY14 time period. For the longer periods (FY79-FY12) the arithmetic mean of daily exchange rates form the FRB H.10 report supply the adjusting rates. Appendix F demonstrates the adjusting rates from the monthly USD currency fluctuation publication and the H.10 average monthly rates are statistically the same. Table 7 below is an example of the USD monthly report on currency fluctuations.

* On January 1, 1999, the euro became the official currency of 11 member states of the European Union with a fixed conversion rate against their national currencies. The euro was adopted by Greece on January 1, 2001. The value of the euro fluctuates according to market conditions against the dollar and all other currencies. Euro notes and coins were introduced to replace national notes and coins on January 1, 2002. The above foreign currency budget rates are based on PBD 660, dated December 9, 2002.
**Adjusting exchange rates for the individual euro-area currencies are no longer provided. Use the fixed conversion rates as follows: 1 Euro = 40.3399 Belgian Francs, 6.55957 French Francs, 1.95583 German Marks, 1936.27 Italian Lire, 2.20371 Netherlands Guilders, 200.482 Portuguese Escudos, 166.386 Spanish Pesetas, 340.750 Greek Drachmas.

Lastly, the OECD provided the long term interest rates required for the forward rates methodology (OECD, 2015). OECD data were available from the online database StatExtracts and provided the long term interest rates as a percent per annum from the monthly monetary and financial statistics. An example of the data is shown in Table 8.

Table 8 OECD Long Term Interest Rates, Percent Per Annum Example

Methods

This research compared six techniques for determining the budgeted foreign exchange rate. They are the forecasts from Global Insight, the status quo, forward rates, ARIMA, the Random Walk model, and futures contract settlement prices. Each technique provides a different approach to forecasting an exchange rate or highlighted in the literature (the Random Walk model is a special type of ARIMA).

Global Insight

Global Insight provides a web-based application from which to view the company's forecasted foreign exchange rates. Included in this application are archived tables from past forecasts. Global Insight publishes forecasts quarterly with quarterly forecasts two years from the published date and annual forecasts nine years from the published date. This thesis applied the annual forecasts as a simulated budgeted rate and compares that rate with the actual monthly rates of the year in question. For example, the FY06 Japanese Yen forecast derived from Table 5 used the 2005 annual exchange rate forecast as the Global Insight 1 year forecast, the 2006 annual exchange rate forecast as the Global Insight 2 year forecast, and the mean of the two as the Global Insight 1-2 year average forecast. This is done for each year and currency in the forecast period.

Status Quo

The current method to determine the budgeted rate consists of a center-weighted-average technique. This technique pulls the average monthly exchange rate for the past five years and the exchange rate 12 months prior from the Federal Reserve's H.10 foreign exchange report. Each of these is weighted equally and combined to form a budgeted exchange rate. The next step is to calculate the forecast error for the five year average and the rate 12 months prior. The forecast error is the sum of squared errors (SSE) between the forecasted rate and the actual rate from previous forecasts. The formula is

$$SSE = \sum (R_{Forecasted} - R_{Observed})^2$$

where $R_{Forecasted}$ is the forecasted exchange rate and $R_{Observed}$ is the actual exchange rate. The summation is over from the most recent observed exchange rate to 60 months previous (e.g. from September 2005 to August 2010). To minimize the forecast error, the weights of the five year and 12 months prior are determined by Excel's add-in Solver. Solver optimizes the weight to minimize the forecast error, the dependent variable, by iteratively changing the weights, as the independent variables. Finally, the results are reviewed for any long term trends or changes to the currency. Adjustments are made to account for fundamental changes (e.g. changing the peg of the Kuwaiti Dinar from the US dollar to a basket of currencies in May 2007 caused the five year average to be a three average in 2010).

Forward Rate

Groshek and Felli found the use of forward contracts can reduce expected costs on the order of 3.5% rather than using a naïve approach (Groshek and Felli, 2000). Their approach is used in this research to compare with the other methods in validating whether forward rate contracts should be used in mitigating currency exchange risks. The forward rate approach begins by determining the total US dollar equivalent of the DoD's foreign commitments by applying forward rates to the estimated foreign currency requirement. The technique assumes the amount budgeted for foreign currency equals the amount liquidated. Next, the technique calculates the difference in values between using the former naïve based approach and the forward rates based approach (represented as V_N^F) with the following equation:

$$V_N^F = \sum_{j=1}^{C} \sum_{k=1}^{T} S_k^j \left\{ r_B^j \left(1 + \frac{k(1-\delta)(i_B^0 - i_B^j)}{T} \right) - r_{L_k}^j \right\}$$

C is the number of foreign currencies in the analysis assigned to an index from 1,2,…,C, and *T* designates the number of periods in the budget cycle. S_k^j is the sum of money in currency *j* (the US is j=0) the DoD must liquidate at the end of period *k*. The budgeted spot rate for country *j* is r_B^j while the liquidation spot rate at the end of period *k* is $r_{L_k}^j$. The variable δ represents the annual discount rate. The difference in the annual interest rate between the US (j=0) and country *j* is $(i_B^0 - i_B^j)$. Interest rates came from *The Economist* in weekly observations. The authors then completed 25,000 Monte Carlo simulations to judge the effectiveness of the model.

This research uses a less complex version for calculating forward rates due to not having the amount of funding required for each year in our study. The following equation was employed to calculate the forward exchange rate used for the budgeted rate:

$$r_j = r_K^{j=0} \frac{1 + i_j}{1 + i_{j=0}}$$

The equation gives the forward exchange rate, r_j, for country *j* using the US dollar spot rate, $r_K^{j=0}$, in annual terms of year *k* and the interest rate, i_j, of country *j* in the month of December before the fiscal year of interest (Feenstra and Taylor, 2008). As an example, for FY06 the Euro forward rate is 0.720868049 as calculated with an $r_K^{j=0}$ of 0.803988 Euro to US dollars annual exchange rate from the FRB H.10 report, an i_j of 3.6893 and a $i_{j=0}$ of 4.23 as the long-term interest rates per annum in December from the OECD monthly monetary and financial statistics dataset.

ARIMA

The ARIMA method integrates an auto regressive, moving average, and differencing parameters to predict future points in a time series. Figure 3 represents the Box and Jenkins process for applying a univariate, time series ARIMA model. It encompasses three phases: identification, estimating and testing, and application.

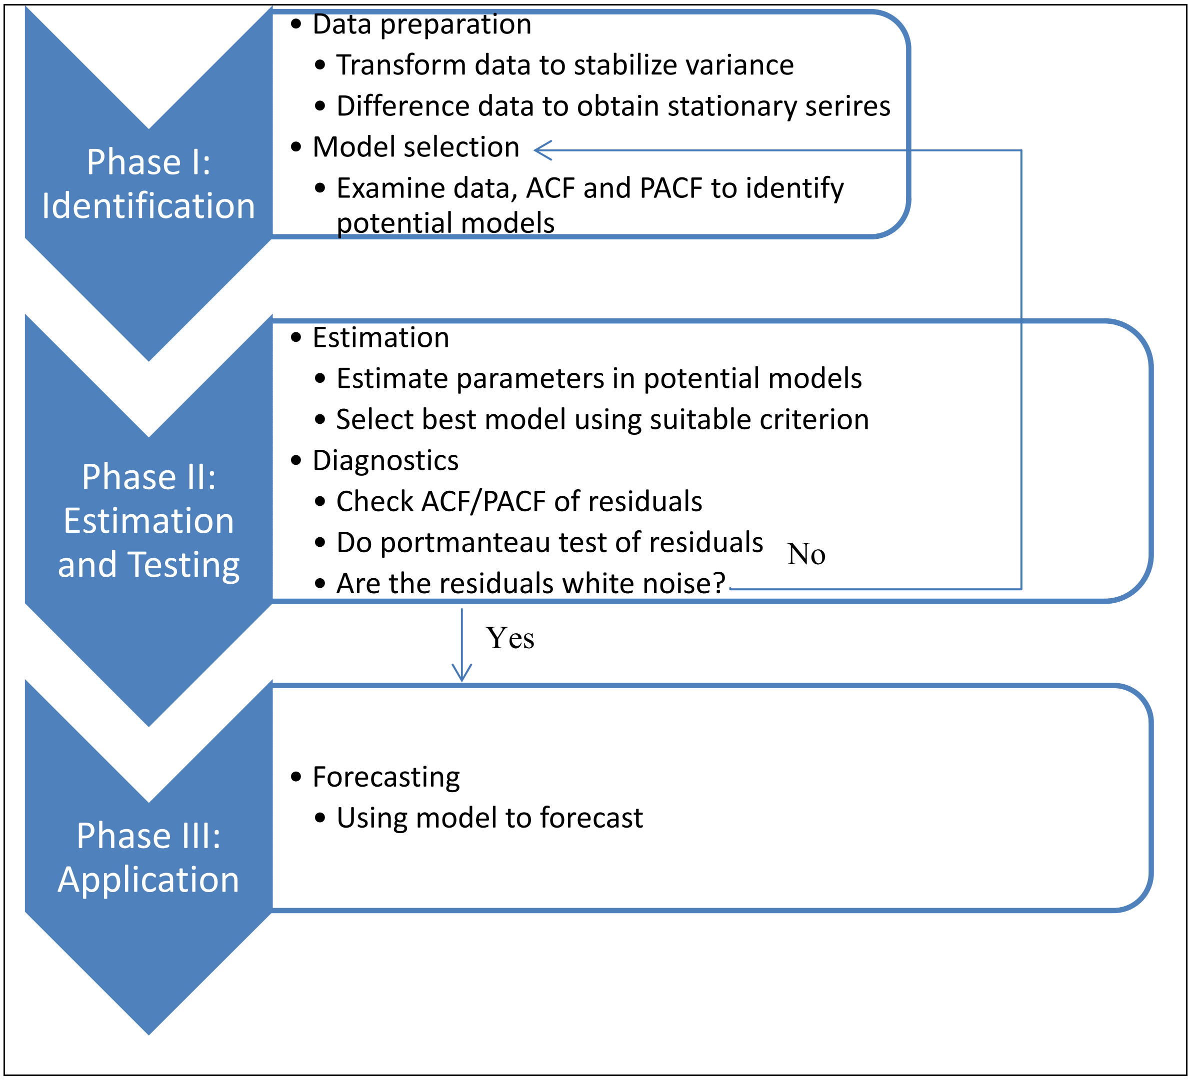

Figure 3 Box-Jenkins process for time series modeling (Makridakis et al, 1998)

Identification consists of data preparation and model selection. Under data preparation, the data are arranged in a time series plot and stabilized, meaning the data must be roughly horizontal along the time axis (x-axis). Plotting the data allows assessment on the stationarity of the data. Stationarity is the lack of change in the mean or variance of the data over time. Stationarity is assessed with the Dickey-Fuller test (Makridakis et al., 1998). The test estimates the following regression model

$$Y_t' = \varphi Y_{t-1} + b_1 Y_{t-1}' + b_2 Y_{t-2}' + \cdots + b_p Y_{t-p}'$$

with Y' as the differenced series Y_t - Y_{t-1}. If Y_t is stationary, then the estimated value of φ will be negative. A φ value close to zero means Y_t needs differencing. Ordinary least squares are used to estimate φ from the regression model. The autocorrelation function (ACF) and partial autocorrelation function (PACF) also test stationarity. The ACF gauges how successive Y values relate to each other and is calculated by:

$$r_k = \frac{\sum_{t=k+1}^{n}(Y_t - \bar{Y})(Y_{t-k} - \bar{Y})}{\sum_{t=1}^{n}(Y_t - \bar{Y})^2}$$

PACF removes the effects of other time lags in the time series to measure the degree of association between Y_t and Y_{t-k}. PACF's formula is:

$$Y_t = b_0 + b_1 Y_{t-1} + b_2 Y_{t-2} + \cdots + b_k Y_{t-k}$$

To show stationarity, the ACF and PACF quickly converge on zero. Should the data appear non-stationary, differencing the data may induce stationary in the mean. Below is the equation for differencing:

$$Y_t' = Y_t - Y_{t-k}$$

Stationarity in the variance can be achieved by transforming the data through a logarithmic or power function. After achieving stationarity, the ACF and PACF are examined for patterns. The patterns may indicate choosing a model for seasonality, auto regression, moving averages, or a mixture. Parameters for the selected are then estimated for the chosen model using the method of least squares. The ARIMA general equation is

$$(1 - \varphi_1 B)(1 - B)Y_t = c + (1 - \theta_1 B)e_t$$

This is an ARIMA(1,1,1) model with φ_1 as the auto regressive parameter, θ_1 as the moving average parameter, and (1-B) as the differencing parameter. B represents the lag operator to incorporate the previous time series element ($BY_t = Y_{t-1}$ for all t>1). The e_t variable is an error term and is assumed to be independent and identically distributed along a normal distribution with a mean of zero. The constant, c, is an overall level for the dependent variable and represents stationarity (the data's mean and/or variance are approximately horizontal along the time axis). The parameter estimates are then tested for significance using the coefficient's standard error. Standard error analysis provides a P-value from which we can calculate statistical significance (a two-sided test was used with an $\alpha = 0.05$). Given the parameter estimates are statistically significant, a diagnostic analysis is done on the ACF/PACF and portmanteau residuals to check for "white noise." The ACF and PACF residuals are plotted and scaled so that variance equals one. Any residuals less than -3 or greater than 3 are outliers. A portmanteau test is an additional analysis of residuals. The portmanteau test uses the Box-Pierce test Q statistic:

$$Q = n \sum_{k=1}^{h} r_k^2$$

where h is the maximum lag being considered and n is the number of observations in the series (Makridakis et al, 1998). If the ARIMA model's residuals are "white noise", then the Q statistic has a chi-squared distribution with (h-m) degrees of freedom (m is the number of parameters in the model). A significant test result from the residual diagnostic indicates an inadequate model, and the process revisits the identification step to discern a better ARIMA model. A model that successfully passes the residual diagnostic is ready for forecasting application.

When choosing between ARIMA models, the Akaike Information Criterion (AIC) provides a measure in choosing the most adequate model (Burnham and Anderson, 2004). The AIC is an estimate of the information loss in a model and is calculated by:

$$AIC = -2LogLikelihood + 2k$$

The term *k* is the number of estimated parameters, including intercept and error terms in the model. A lower AIC value guards against information loss and the better the model at estimating (SAS Institute Inc, 2014).

For this research, Y_t is the forecasted exchange rate of interest and *t* is the time period of interest. Y_t is calculated for a budget forecast rate and compared to the actual rate to calculate the APE. Time-lagged foreign exchange rates make up the explanatory variables for estimating the ARIMA parameters. Annual forecasts were done using the JMP ARIMA model grouping. The model group allow for testing 27 separate ARIMA models for each currency by fiscal year (from ARIMA(0,0,0) to ARIMA (2,2,2) or 3^3 possibilities). The model with the lowest AIC provided the estimate for the budgeted rate. The immediate estimate from the model gave the 1 year estimate while the Y_{t+1} provided the 2 year estimate. These two estimates were then averaged to arrive at a 1-2 year average estimate as another budgeted rate to test against.

Random Walk

The Random Walk method is a special type of ARIMA model. ARIMA(0,1,0) represents the Random Walk and lacks an autoregressive and moving average parameters but maintains a difference (Nau, 2014). Random Walks can have extended periods of apparent trends which unpredictably change direction. The mathematical representation is:

$$Y_t = Y_{t-1} + \varepsilon_t$$

where the forecasted value, Y_t, equals the previous value, Y_{t-1}, plus an error term, ε_t. In order to generate a budgeted rate, the thesis uses historical exchange rates to derive an error term. This error term is added to the last data point for the exchange rate to create a budgeted exchange rate. The immediate estimate from the model gave the 1 year estimate while the Y_{t+1} provided the 2 year estimate. These two estimates were then averaged to arrive at a 1-2 year average estimate as another budgeted rate to test against.

Futures

The futures method uses the settle rate from Table 6 as the key input in producing a budgeted rate. The intuition of using futures data is the price of the futures contract aggregates the information of the buyers and sellers of the contract in divining the true value of the underlying currency. The data contains daily settle prices, which we averaged annually from January 1st to December 31st and for the month of October as the budgeted rate for the following fiscal year. For example, the settle prices from 1 January 2004 to 31 December 2004 were averaged for the Futures Annual Mean 1 Year forecast of FY06. The average settle price for the month of October 2004 was used as the Futures October Mean for FY06.

Comparison

The comparison uses the median of the Absolute Percent Error (APE):

$$APE = \left|\frac{X_{actual} - X_{forecasted}}{X_{actual}}\right|$$

To compute the median, the APEs are arranged from lowest to largest APE from APE_1, APE_2, …, APE_n before choosing the APE at $\frac{n}{2}$ as the median. If $\frac{n}{2}$ does not provide a whole number (e.g.if n=9, $\frac{9}{2} = 4.5$), then the average between the two nearest APEs serves as the median (e.g. $\frac{APE_4+APE_5}{2}$). After calculating the median APE of all six methods, the thesis compares the accuracy of forecasting exchange rates. The lowest median indicates the more accurate method of forecasting as the forecast is relatively closer to the actual rate. Other considerations include the frequency of over estimating against under estimating the actual rate. Ideally, the forecast would match the actual rate although, given the uncertainty of requesting additional funds from Congress during the execution phase, over estimating the required amount of currency is preferred to under estimating

After calculating the APE for each currency by method, the thesis performed a bootstrap analysis on the median to examine whether the methods are from the same population in a statistically significant manner. The bootstrap method resample's each method's APEs with replacement to create a large number of sample statistics (Singh and Xie, 2008). In this case, the median is resample 10,000 times, and find a 95% percentile confidence interval (using α=2.5% two-tailed interval). The bootstrap sample medians with confidence intervals are then compared to the other methods by overlapping confidence intervals. Should one method's confidence interval overlap another method, the two methods may come from the same population, and are therefore not significantly different. The JMP® program draws on the entire APE distribution as the bootstrap sample for every bootstrap iteration (i.e. an APE sample of 752 means each bootstrap sample will also have 752 samples but with replacement for each sample taken from the original APE sample) (Ramsey, 2013). Fractional weighting was not used from the original sample APE's distribution for the bootstrap.

Finally, the thesis compares methods by how often the budgeted rate is greater than the actual rate. Each month will show which rate is higher. Assuming a risk adverse DoD, a higher actual rate is preferred. For example, a ¥1,000 requirement in US dollars at 110 Yen per dollar budgeted rate equals a budget of $9.09. If the actual rate were 100 yen per dollar at the time of execution, the amount needed to cover the requirement is $10. For each method and each time period, the chance of budgeting too little is calculated by dividing the number of months the budgeted rate is greater than the actual rate by the total number of months in that period. A lower percent decreases chance of budgeting too little.

Long Term Study

Given the small time frame, a broader understanding of the problem required greater data points to reach a firm decision. From FY06 to FY14 only offered nine opportunities to calculate a budgeted rate. Extending the study period to FY91 offered 16 additional years and to FY79 offered 28 additional opportunities at formulating and testing budgeted rates through the various methods. These additional study periods, however, could not use all of the currencies and methods as the FY06 to FY14 study period.

Study Period from FY91 to FY12

The study period from FY91 to FY12 encompasses a total of 22 years, or 22 attempts at forecasting a budgeted rate. While data for some countries extend to this date and beyond, only the Japanese Yen and United Kingdom Pound were examined. These two currencies could be used for each method compared in this time period. Methods for this time period compose of ARIMA, Random Walk, futures, forward rates, and the status quo. The Global Insight database did not extend as far back as FY91. Each methodology forecasted a budgeted rate for FY91 which was then compared to the FRB H.10 monthly averages to derive an APE for that month. The monthly APEs were then averaged for the fiscal year. The mean and median were both recorded in order to compare the different methods. To identify whether methods were statistically different, a bootstrap with 10,000 samplings for each method's median provided a distribution of the median to compare against other methods. Any median distribution overlapping the median distribution of a different method could be considered statistically the same.

Study Period from FY79 to FY12

The study period from FY79 to FY12 encompasses a total of 34 attempts at forecasting a budgeted rate. During this period, the Japanese Yen and United Kingdom Pound are again the currencies examined. The methods compose of ARIMA, Random Walk, futures, and the status quo. The long term interest rates data did not contain the rate for Japan before 1989 precluding the use of the forward rates methodology earlier than FY91. Each methodology forecasted a budgeted rate for FY91 which was then compared to the FRB H.10 monthly averages to derive an APE for that month. The monthly APEs were then averaged for the fiscal year. The mean and median were both recorded in order to compare the different methods. To identify whether methods were statistically different, a bootstrap with 10,000 samplings for each method's median provided a distribution of the median to compare against other methods. Any median distribution overlapping the median distribution of a different method could be considered statistically the same.

Summary

Using five sets of data sources, the thesis compares six methodologies in order to recommend the one with the lowest median APE. The forecasts from Global Insight are the first of six forecast methodologies tested. The other five include the status quo forward rate, ARIMA, the Random Walk, and futures settlement prices. The thesis contrasts these forecasts against the actual rate to find the monthly APE. The median APE allows comparison of the six techniques in terms of accuracy. Objectivity and complexity of the techniques provide additional criteria to compare the six techniques. After reviewing the APE, simplicity, and risk in budgeting too little, the thesis will recommend a technique for use by the DoD.

IV. Results

Chapter 4 states the results of applying each methodology. The chapter provides each method's MAPE compared to the status quo, before providing a comparison of all methodologies. A summary of the chapter briefly reviews the material covered in this chapter.

Global Insight

Table 9 compares the Global Insight 1 year, 2 year, and 1-2 year average forecast rate mean APE (MAPE) against the status quo MAPE from Fiscal Year 2006 to FY 2014 (FY06 to FY14).

Table 9 Global Insight 1 Year, 2 Year, 1-2 Year Average and Status Quo MAPE for FY06 - FY14 and Probability of Budgeted Rate Greater than the Adjusted Rate

FY	Status Quo MAPE	Status Quo Percent Budget Rate > Adjusted Rate	Global Insight 1 Year MAPE	Global Insight 1 Year Percent Budget Rate > Adjusted Rate	Global Insight 2 Year MAPE	Global Insight 2 Year Percent Budget Rate > Adjusted Rate	Global Insight 1-2 Year Average MAPE	Global Insight 1-2 Year Average Percent Budget Rate > Adjusted Rate

14	6.56%	72.92%	10.22%	27.08%	10.14%	10.42%	9.86%	16.67%
Average	10.38%	59.49%	8.42%	47.69%	9.12%	40.74%	8.33%	46.76%

For example, the 2004 4th Quarter Cost International Forecast Table provided the Global Insight 1 and 2 year forecast for FY06 (2005 and 2006 forecasted exchange rates). Furthermore, the table includes the percentage of forecasted exchange rates exceeding the actual exchange rates. This percentage is the probability of budgeting enough funding for requirements given the applied forecasted rate as the budgeted rate as shown in Figure 1. Lastly, the countries for this data include the EU, Japan, South Korea, and the UK.

Averaging the 1 year and 2 year forecasted rates provides the best MAPE of the Global Insight data while the status quo has the highest percentage of a higher budgeted rate than adjusted rate. The distribution of Global Insight APEs gave reason to doubt the mean as a true gauge of the resulting data's central tendency. Figure 4 provides the distribution of APEs along with a box plot and normal curves. The median (50.0% quantile) is less than the mean for each of the Global Insight forecasted budgeted rates. Since normality is not present, nonparametric measures are the appropriate approach to comparing methods. The medians provide a closer approximation of the central tendency of the results, while the use of a mean would consistently skew the data to the right of the results central mass. Also, since the results are not normally distributed, the use of standard deviations does not lend itself to an adequate measure of dispersion. The inter-quartile range (IQR) is the preferred method in this research in determining the dispersion of the results.

Figure 4 Printout of the Global Insight APE Distribution

Forward Rate

Table 10 compares the forward rate 1 year forecast rate MAPE against the status quo MAPE from FY06 to FY14. For example, the ratio of December 2004 long-term annual interest rates multiplied by the Annual FRB H.10 rate calculates the FY06 forecasted rate. Furthermore, the table includes the percentage of forecasted exchange rates exceeding the actual exchange rates. This percentage gives the probability of budgeting enough funding for requirements given the applied forecasted rate as the budgeted rate. Lastly, the countries for this data include Denmark, the EU, Japan, Norway, South Korea, and the UK.

Table 10 Forward Rate and Status Quo MAPE for FY06 - FY14 and Probability of Budgeted Rate Greater than the Adjusted Rate

FY	Status Quo MAPE	Status Quo Percent Budget Rate > Adjusted Rate	Forward Rate 1 Year MAPE	Forward Rate 1 Year Percent Budget Rate > Adjusted Rate
6	8.10%	80.28%	6.11%	54.93%
7	14.19%	83.33%	7.62%	81.94%
8	16.27%	91.67%	14.45%	87.50%
9	13.43%	56.94%	16.85%	34.72%
10	9.06%	68.06%	10.96%	23.61%
11	9.15%	66.67%	8.95%	81.94%
12	6.09%	41.67%	4.54%	76.39%
13	5.61%	19.44%	5.35%	13.89%
14	5.58%	54.79%	8.26%	63.01%
Average	9.72%	62.54%	9.23%	57.55%

The forward rate calculation has a lower MAPE and percentage of a higher budgeted rate than adjusted rate compared to using the status quo. Similar to the Global Insight results, the APEs for the forward rate calculation also do not show a normal distribution. Figure 5 provides a graph of the APE distribution. Again the median is lower than the mean and provides a better gauge of the central tendency of the results.

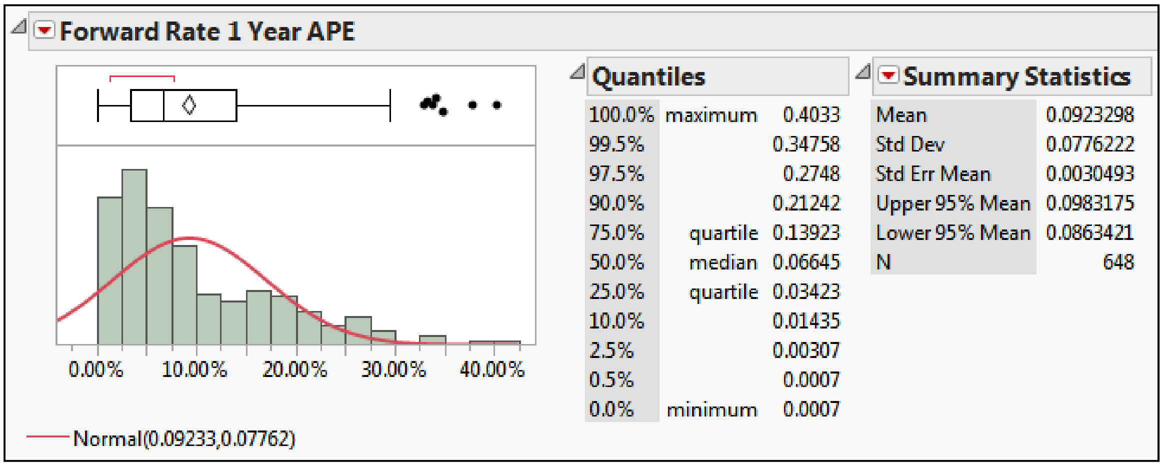

Figure 5 Printout of the Forward Rate APE Distribution

ARIMA

Table 11 compares the ARIMA 1 year, 2 year, and 1-2 year average forecasted rate MAPE against the status quo MAPE from FY06 to FY14. For each year and each currency, 27 different ARIMA models were made from ARIMA (0,0,0) to ARIMA (2,2,2) and ranked by AIC. The model with the lowest AIC was then chosen to forecast a budgeted rate for that currency for that year. The process was then repeated for each year and currency. For example, the time series of annual FRB H.10 foreign exchange rates until 2004 provides the data for an ARIMA model to forecast 1 year and 2 year rates for FY06 (2005 and 2006). Furthermore, the table includes the percentage of forecasted exchange rates exceeding the actual exchange rates. This percentage gives the probability of budgeting enough funding for requirements given the applied forecasted rate as the budgeted rate. Lastly, the countries for this data include Denmark, the EU, Japan, Norway, Singapore, South Korea, and the UK.

Table 11 ARIMA 1 Year, 2 Year, 1-2 Year Average and Status Quo MAPE for FY06 - FY14 and Probability of Budgeted Rate Greater than the Adjusted Rate

FY	Status Quo MAPE	Status Quo Percent Budget Rate > Adjusted Rate	ARIMA 1 Year MAPE	ARIMA 1 Year Percent Budget Rate > Adjusted Rate	ARIMA 2 Year MAPE	ARIMA 2 Year Percent Budget Rate > Adjusted Rate	ARIMA 1-2 Year Average MAPE	ARIMA 1-2 Year Average Percent Budget Rate > Adjusted Rate
6	8.03%	83.13%	6.68%	59.04%	9.76%	66.27%	8.17%	61.45%
7	13.82%	85.71%	11.85%	85.71%	16.60%	85.71%	14.22%	85.71%
8	16.19%	92.86%	17.60%	86.90%	21.51%	84.52%	19.55%	86.90%
9	12.52%	63.10%	15.08%	35.71%	16.83%	40.48%	15.70%	35.71%
10	9.15%	72.62%	7.24%	28.57%	10.46%	46.43%	7.25%	36.90%
11	10.21%	71.43%	14.68%	98.81%	18.83%	100.00%	16.75%	100.00%
12	7.13%	50.00%	4.52%	88.10%	6.41%	76.19%	5.38%	80.95%
13	5.80%	30.95%	7.52%	14.29%	7.54%	33.33%	6.71%	30.95%
14	5.17%	54.12%	8.97%	63.53%	10.81%	65.88%	9.81%	65.88%
Average	9.78%	67.10%	10.46%	62.30%	13.19%	66.53%	11.51%	64.94%

The status quo has a lower MAPE and a greater chance of a higher budgeted rate than adjusted rate compared to using ARIMA 1 year, 2 year, and 1-2 year average forecasts. As in the above methods, the APEs from the ARIMA results do not show a normal distribution. Figure 6 provides the APE distributions for each ARIMA method. The medians for each ARIMA method are also lower than the mean and provide a measure closer to the center mass of the APE distribution.

Figure 6 JMP® Printout of the ARIMA APE Distribution

Random Walk

Table 12 compares the Random Walk model 1 year, 2 year, and 1-2 year average forecasted rate MAPE against the status quo MAPE from FY06 to FY14. For example, the time series of annual FRB H.10 foreign exchange rates until 2004 provides the data for an ARIMA(0,1,0) model to forecast 1 year and 2 year rates for FY06 (2005 and 2006). Furthermore, the table includes the percentage of forecasted exchange rates exceeding the actual exchange rates. This percentage gives the probability of budgeting enough funding for requirements given the applied forecasted rate as the budgeted rate. Lastly, the countries for this data include Denmark, the EU, Japan, Norway, Singapore, South Korea, and the UK.

Table 12 Random Walk 1 Year, 2 Year, 1-2 Year Average and Status Quo MAPE for FY06 - FY14 and Probability of Budgeted Rate Greater than the Adjusted Rate

Figure 7 JMP® Printout of the Random Walk APE Distribution

The 1 year forecasted rate provides the best MAPE of the Random Walk model while the status quo has the highest percentage of a higher budgeted rate than adjusted rate. The Random Walk model has an APE distribution skewed right similar with the above results. The mean is higher than the median, as shown in Figure 7, with the median as a better representation of the central tendency.

Futures

Table 13 compares future markets annual average and October average forecasted rate MAPE against the status quo MAPE from FY06 to FY14. For example, the futures data uses the average price of the following month's futures contract from 2004 as the forecast rate for FY06 (2005 and 2006). Furthermore, the table includes the percentage of forecasted exchange rates exceeding the actual exchange rates. This percentage gives the probability of budgeting enough funding for requirements given the applied forecasted rate as the budgeted rate. Lastly, the countries for this data include Denmark, the EU, Japan, and the UK.

Table 13 Futures Annual and October Average and Status Quo MAPE for FY06 - FY14 and Probability of Budgeted Rate Greater than the Adjusted Rate

FY	Status Quo MAPE	Status Quo Percent Budget Rate > Adjusted Rate	Futures Annual Average 1 Year MAPE	Futures Annual Average 1 Year Percent Budget Rate > Adjusted Rate	Futures October Average 1 Year MAPE	Futures October Average 1 Year Percent Budget Rate > Adjusted Rate
6	5.73%	77.78%	4.52%	30.56%	4.33%	33.33%
7	10.96%	66.67%	8.23%	66.67%	9.15%	66.67%

9	13.96%	66.67%	16.91%	50.00%	16.97%	41.67%
10	12.36%	58.33%	12.84%	38.89%	8.02%	55.56%
11	12.47%	52.78%	7.55%	77.78%	6.58%	50.00%
12	8.48%	41.67%	5.63%	77.78%	3.83%	47.22%
13	8.03%	0.00%	7.88%	11.11%	8.37%	11.11%
14	6.26%	63.89%	10.89%	63.89%	10.27%	61.11%
Average	10.20%	58.02%	9.55%	56.79%	8.79%	51.23%

The October average forecasted rate provides the best MAPE of the futures contracts model while the status quo has the highest percentage of a higher budgeted rate than adjusted rate. The APEs for this method also skew right with the mean above the median as shown in Figure 8. For comparison, using medians rather than the mean gives a better assessment of the differences between methodologies.

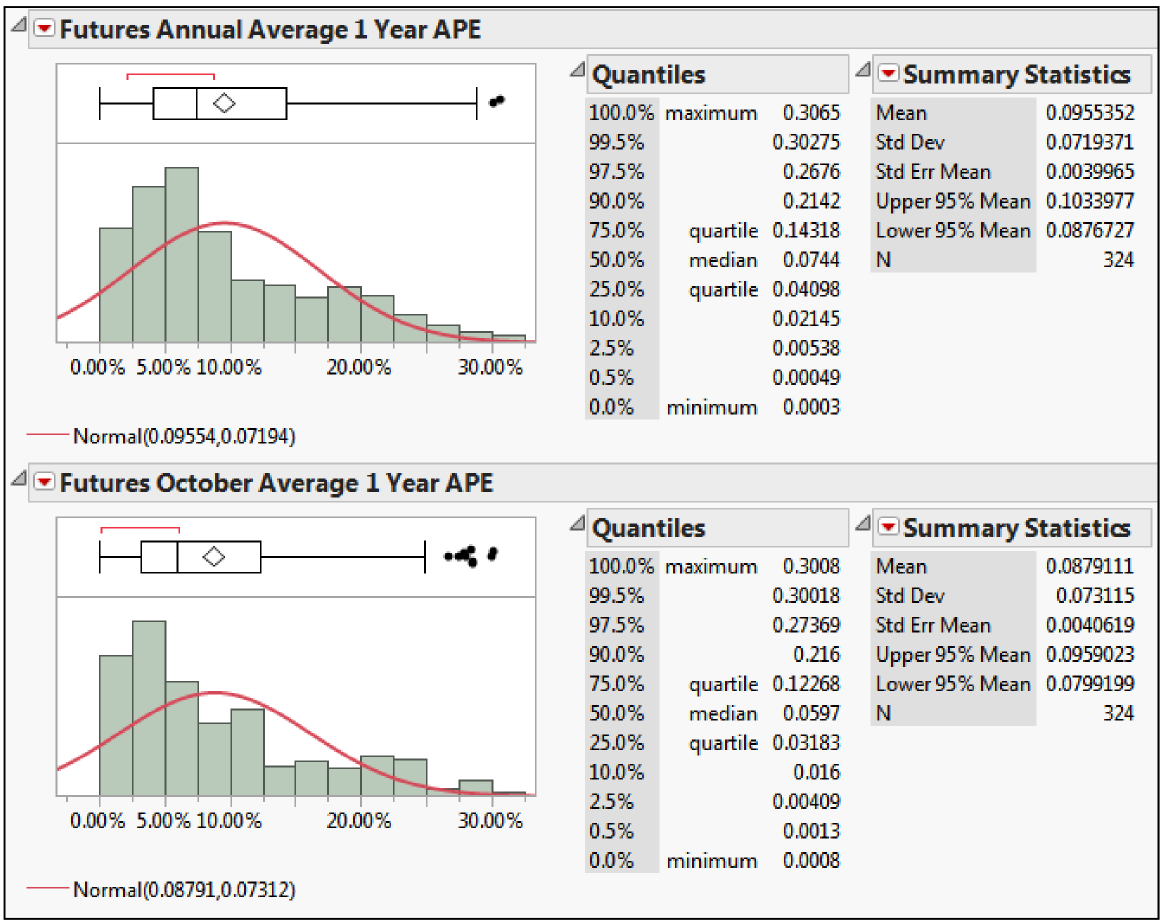

Figure 8 JMP® Printout of the Futures APE Distribution

Comparison

Table 14 presents each methodology's MAPE according to country over the time period. A highlighted MAPE is the lowest error between all available methods for that country. Overall, Global Inisght's 1-2 year average forecast provides the lowest MAPE. Only the ARIMA 2 year and 1-2 year average had worse MAPEs than the status quo.

Table 14 Average MAPE for Each Country by Methodology from FY06 to FY14 with the Lowest MAPE Highlighted

Table 15 presents a comparison between the methods using only the currencies from the EU, Japan, and the UK. Every methodology calculated a forecast for these countries and provides a fairer comparison as opposed to Table 14. The Global Insight 1 year forecast provided the best estimates for the UK Pound while the Global Insight 1-2 year average was the best forecast for the Euro, Japanese Yen, and overall average.

Table 15 Average MAPE for the EU, Japan, and the UK by Methodology from FY06 to FY14 with the Lowest MAPE Highlighted

	MAPE from FY06 to FY14												
Country	Status Quo	Global Insight 1 Year	Global Insight 2 Year	Global Insight 1-2 Year Mean	Random Walk 1 year	Random Walk 2 year	Random Walk 1-2 Mean year	Forward Rates	ARIMA 1 year	ARIMA 2 year	ARIMA 1-2 Year Mean	Futures Annual Mean 1 Year	Futures October Mean 1 Year

As mentioned above, the mean is not the best measure of central tendency for each month's results. The APE distributions are skewed to the right. Comparing medians offer a better approach to choosing the lowest APE methodology. Table 17 examines the median APE for currencies with every available methodology, and, as in Table 15, the overall best method is the average October futures contract.

Table 16 recreates Table 14 with medians rather than means. Judging by the average (mean) of each country's median, the best overall method is the Global Insight forecast 1 year forecast as opposed to the average 1-2 year forecast. Table 17 examines the median APE for currencies with every available methodology, and, as in Table 15, the overall best method is the average October futures contract.

Table 16 Median APE for Each Country by Methodology from FY06 to FY14 with the Lowest Median APE Highlighted

Finally, a medians comparison was accomplished via a bootstrap to distinguish which which methods are statistically the same or different. Figure 9 illustrates the results of the bootstrap analysis based on a 95% confidence interval (the upper bound is 97.5% and the lower bound is 2.5%) across all APEs for all the countries available to a method. Methods that can be considered statistically similar are connected by horizontal lines. The medians are different from Table 16 and Table 17 due to aggregating each country's APE for the entire time frame, rather than country specific. Line "A" connects the average futures contract settlement prices in October or annually, the Global Insight forecast, a Random Walk model, or forward rates can is statistically no different than any other, and each has a lower median APE interval than the status quo. The ARIMA models can be thought of as statistically the same as the status quo (line "C" or "D") with care given to including or excluding the ARIMA 1 year or ARIMA 2 year forecast methods. All methods connected by line "A" have a lower median APE than the status quo. Table 18 is the amount of percentage points the median of each method on line "A" is lower than the status quo median as taken from Table 17 examines the median APE for currencies with every available methodology, and, as in Table 15, the overall best method is the average October futures contract.

Table 16 It also shows the opportunity cost of the status quo of using the status quo over the method (using the overall median APE from each method against all of the currencies in the FY13 FCF account).

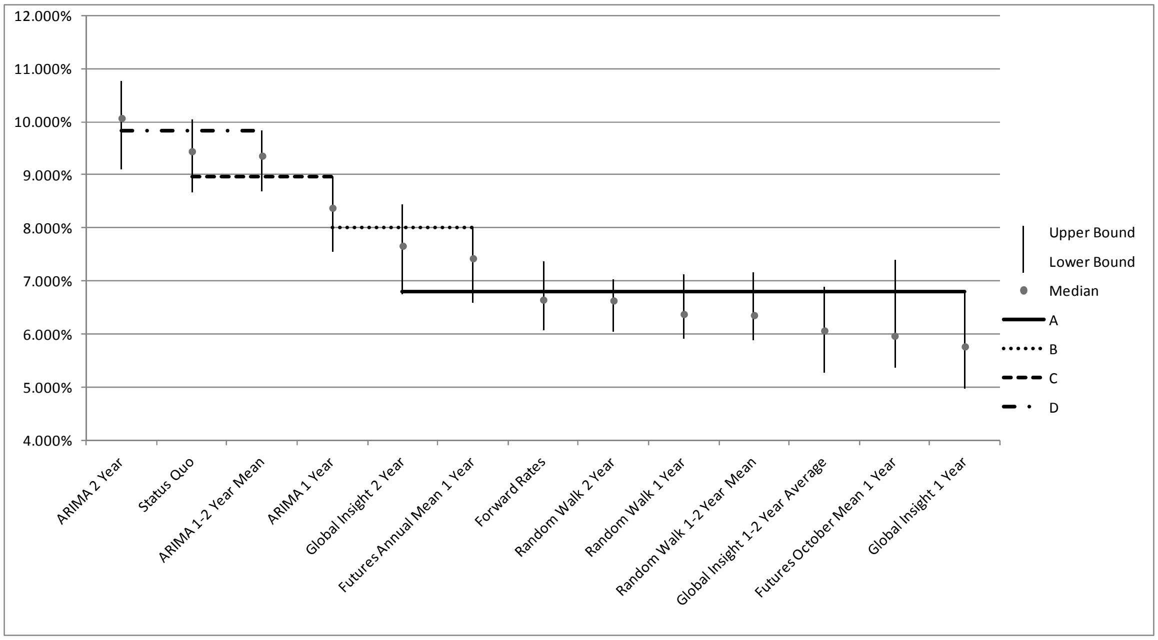

Figure 9 Medians Comparison between Methodologies Based with 95% Confidence Bounds

Table 18 The Median APE Percent of Line A Methods and the Associated Opportunity Cost of the Status Quo Over Each Method FY06-FY14

	Global Insight			Random Walk			Forward Rate	Futures	
	1 Year	2 Year	1-2 Year	1 Year	2 Year	1-2 Year		Annual	Oct
Percent Lower than Status Quo	3.38	2.27	3.08	2.71	0.81	2.41	0.70	2.05	3.26
Opportunity Cost ($M)	36.1	25.0	33.9	29.8	8.9	26.5	7.7	22.5	34.8

Long Term Comparison

The long term comparisons only include the currencies for Japan and the United Kingdom. This is due to the unavailability of data for each method for the other currencies. Furthermore, the Global Insight data is not available for the time period and that method is excluded from the analysis. Using the results from the short term study period, median APEs are used as the primary metric in comparing methods as opposed to the MAPE.

Comparison from FY91 to FY12

The FY91 to FY12 period uses the status quo, Random Walk model, forward rates, ARIMA, and futures data as the methods of comparison. The lowest median is highlighted in yellow. Consistent with the shorter time period findings, the average futures contract settlement price in October provides the lowest median APE as shown in Table 19. A comparison of the method medians by currency in Table 20 also highlights the average futures contract in October as the lowest median APE for the Pound while the Random Walk 2 year forecast has the lowest median for the Yen.

Table 19 Median APE Combining All Countries from FY91 to FY12 with Inter-Quartile Range

	Median APE for All Countries									
	Status Quo	Random Walk 1 year	Random Walk 2 year	Random Walk 1-2 Mean year	Forward Rates	ARIMA 1 year	ARIMA 2 year	ARIMA 1-2 Year Mean	Futures Annual Mean 1 Year	Futures October Mean 1 Year
Median (IQR)	10.285 (5.728-15.643)	8.73 (4.04-14.725)	8.86 (4.213-16.43)	8.815 (3.695-15.09)	9.69 (3.91-16.458)	10.065 (6.02-16.258)	11.215 (6.718-17.163)	10.41 (6.498-16.76)	9.525 (4.243-14.908)	7.975 (3.54-12.82)

Table 20 Median APE by Country from FY91 to FY12 with Inter-Quartile Range

	Median APE for Countries with All Methods									
Country	Status Quo	Random Walk 1 year	Random Walk 2 year	Random Walk 1-2 Mean year	Forward Rates	ARIMA 1 year	ARIMA 2 year	ARIMA 1-2 Year Mean	Futures Annual Mean 1 Year	Futures October Mean 1 Year
JAPAN	12.22 (5.94-18.93)	10.31 (5.23-15.97)	9.27 (4.09-20.58)	9.92 (3.58-17.61)	13.63 (6.15-19.033)	12.00 (6.59-19.79)	13.85 (6.84-22.88)	13.19 (6.83-21.18)	12.10 (6.59-18.14)	9.45 (4.2-14.045)
UK	9.04 (5.55-13.52)	7.86 (3.52-12.56)	8.53 (4.26-12.96)	8.15 (3.73-12.94)	6.065 (2.745-13.488)	8.95 (4.92-13.29)	9.60 (6.26-13.58)	8.64 (6.44-13.23)	6.81 (3.18-12.36)	6.315 (3.123-11.325)

Next, a medians comparison was accomplished to distinguish which methods are statistically different. Figure 10 illustrates the results of the bootstrap analysis based on a

95% confidence interval. Methods that can be considered statistically similar are connected by horizontal lines. The best methods are the average futures contract in October and the Random Walk models. Horizontal lines connect the annual average futures contract and the forward rate method to every other model, therefore those methods were not considered different than the status quo. The ARIMA 2 year forecast performed the worst and could be considered by itself, or with the forward rates, status quo, annual average futures contract, and ARIMA 1 year and 1-2 year average forecasts. Table 21 is the amount of percentage points the median of each method on line "A" is lower than the status quo median as taken from Table 19. It also shows the opportunity cost of using the status quo over the lower APE methods (using the overall median APE from each method against all of the currencies in the FY13 FCF account).

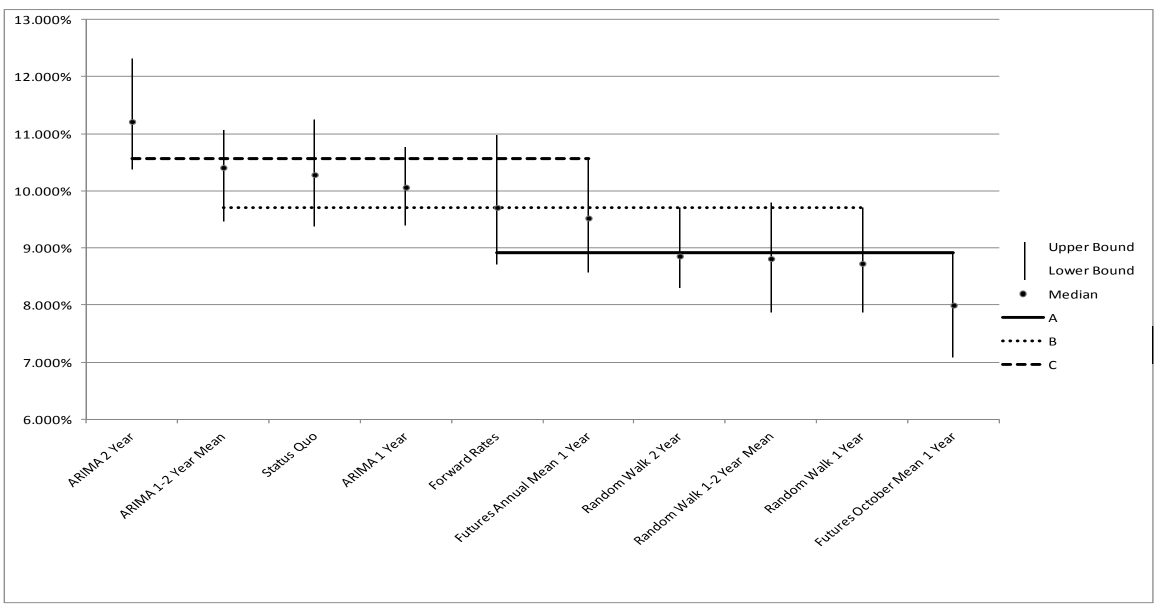

Figure 10 FY91-FY12 Medians Comparison Between Methodologies Based with 95% Confidence Bounds

Table 21 The Median APE Percent of Line A Methods and the Associated Opportunity Cost of the Status Quo Over Each Method FY91-FY12

	Random Walk			Futures Oct
	1 Year	2 Year	1-2 Year	
Percent Lower than Status Quo	1.56	1.43	1.47	2.31
Opportunity Cost ($M)	17.1	15.7	16.2	25.3

Table 22 presents the number of months the method's budgeted exchange rate is greater than the actual exchange rate. Should the actual exchange rate be lower, the US dollars allocated would not cover the requirement. For example, a ¥1,000 requirement in US dollars at 110 Yen per dollar equals a budget of $9.09. If the actual rate were 100 yen per dollar at the time of execution, the amount needed to cover the requirement is $10. The table provides the chance the method's budget would allocate enough funding to cover the actual expenses during the year of execution. Highlighted in yellow, the Random Walk 2 year forecast provides the lowest chance of the budgeted rate being higher than the actual rate.

Table 22 Comparison of Each Methods Chance of a Greater Budgeted Rate than the Actual Rate from FY91 to FY12

FY	Status Quo	Random Walk 1 Year	Random Walk 2 Year	Random Walk 1-2 Year Mean	Forward Rates	ARIMA 1 Year	ARIMA 2 Year	ARIMA 1-2 Year Mean	Futures Annual Mean 1 Year	Futures October Mean 1 Year
Percent Budget Rate > Actual Rate	57.58%	57.01%	44.70%	51.70%	63.64%	52.46%	48.30%	50.57%	62.88%	55.49%

Comparison from FY79 to FY12

The FY79 to FY12 period uses the status quo, Random Walk model, ARIMA, and futures data as the methods of comparison. Forward rates for the Bank of Japan were unavailable before 1989 from the OECD data file. The lowest median is highlighted in yellow. The average futures contract settlement price in October provides the lowest median APE as shown in Table 23. A comparison of the method medians by currency in Table 24 also highlights the average futures contract in October as the lowest median APE.

Table 23 Median APE Combining All Countries from FY79 to FY12 with Inter-Quartile Range

	Median APE for All Countries								
	Status Quo	Random Walk 1 year	Random Walk 2 year	Random Walk 1-2 Mean year	ARIMA 1 year	ARIMA 2 year	ARIMA 1-2 Year Mean	Futures Annual Mean 1 Year	Futures October Mean 1 Year
Median (IQR)	11.3 (6.018-18.508)	11.435 (5.275-18.013)	11.435 (5.403-20.568)	11.66 (4.713-18.708)	10.945 (6.063-18.758)	13.1 (7.148-24.16)	12.095 (6.805-21.443)	11.12 (6.805-21.443)	10.085 (4.723-16.22)

Table 24 Median APE by Country from FY79 to FY12 with Inter-Quartile Range

	Median APE for Countries with All Methods								
Country	Status Quo	Random Walk 1 year	Random Walk 2 year	Random Walk 1-2 Mean year	ARIMA 1 year	ARIMA 2 year	ARIMA 1-2 Year Mean	Futures Annual Mean 1 Year	Futures October Mean 1 Year

Next, a medians comparison was accomplished to distinguish which methods are statistically different. Figure 11 illustrates the results of the bootstrap analysis based on a 95% confidence interval. Methods that can be considered statistically similar are connected by horizontal lines. The average futures contract in October is statistically similar to the ARIMA 1 year forecast, the average annual futures contract settlement price, and the status quo. The ARIMA 2 year forecast is not connected by horizontal line to another method and can be considered statistically different. The Random Walk models, status quo, annual average futures contract, and ARIMA 1 year and 1-2 year average forecasts are not statistically different from each other. The median APE of the futures contracts in October method is 1.2% lower than the status quo median resulting in $13.7 million opportunity cost (assuming the median of the method applied to all currencies in the FY13 FCF). At a 90% confidence interval, Figure 12, the futures contract methods and ARIMA 1 year forecast are statistically different from the status quo.

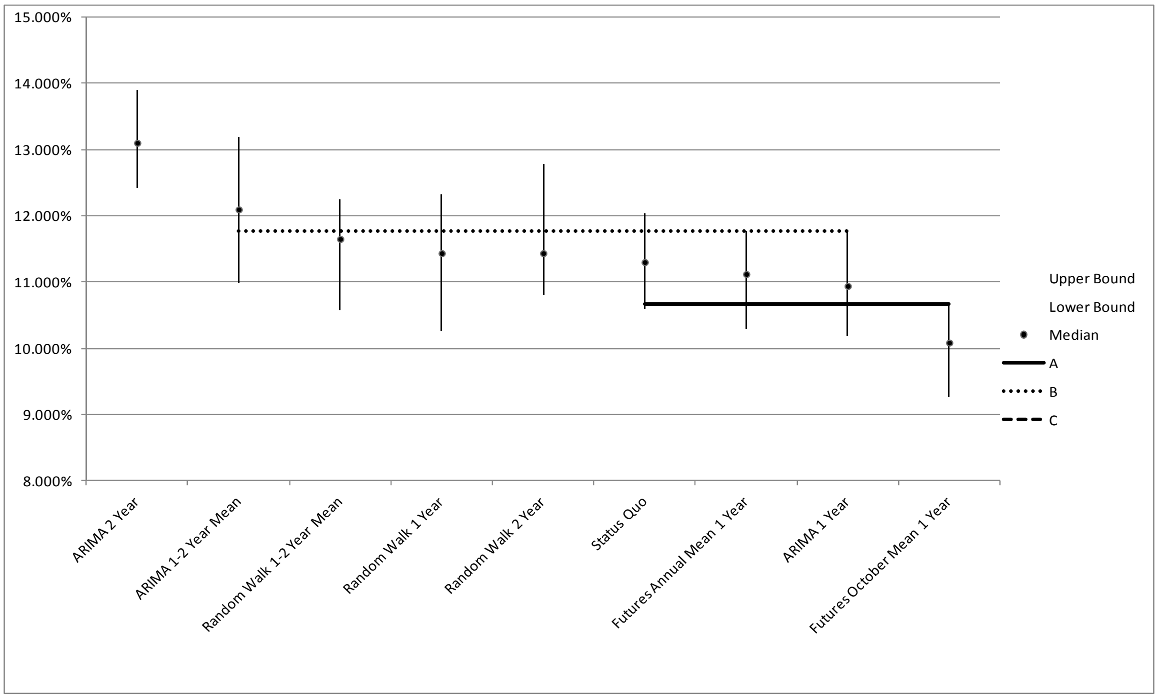

Figure 11 FY79-FY12 Medians Comparison Between Methodologies Based with 95% Confidence Bounds

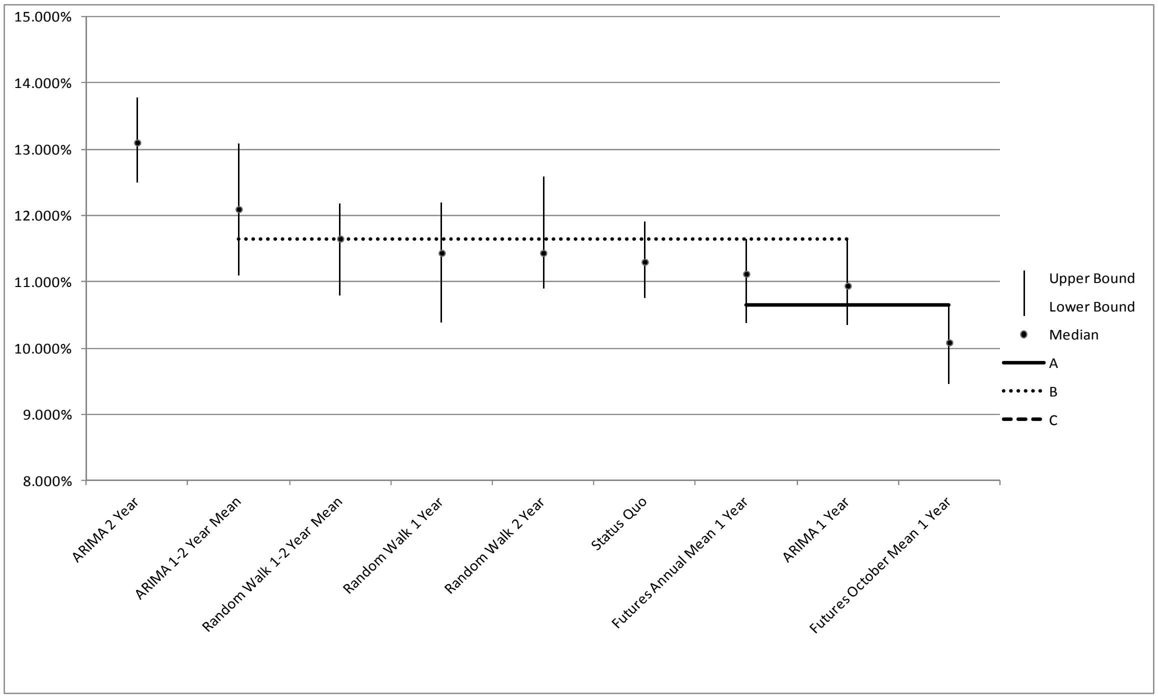

Figure 12 FY79-FY12 Medians Comparison Between Methodologies Based with 90% Confidence Bounds

Table 25 presents the number of months the method's budgeted exchange rate is greater than the actual exchange rate. Highlighted in yellow, the Random Walk 2 year forecast provides the lowest chance of the budgeted rate being higher than the actual rate.

Table 25 Comparison of Each Methods Chance of a Greater Budgeted Rate than the Actual Rate from FY79 to FY12

FY	Status Quo	Random Walk 1 Year	Random Walk 2 Year	Random Walk 1-2 Year Mean	ARIMA 1 Year	ARIMA 2 Year	ARIMA 1-2 Year Mean	Futures Annual Mean 1 Year	Futures October Mean 1 Year
Percent Budget Rate > Actual Rate	59.68%	54.53%	45.10%	50.61%	51.72%	49.14%	50.61%	60.05%	55.02%

Summary

The Global Insight's forecasts provide the lowest MAPE and median APE. The average futures contract in October provided the lowest median APE when comparing the methods with only against the Euro, Pound, and Yen. Both can be considered statistically the same along with the Random Walk and forward rate methods using a 95% confidence interval around each method's medians. All of those models have lower median APEs than the status quo. The ARIMA models performed no better, or worse, than the status quo.

When viewed over a longer time horizon, the average futures contract in October consistently displays lower median APEs than the other methodologies while the ARIMA 2 year forecast is consistently higher. From FY91-FY12, the medians of the October futures contracts, forward rate, and Random Walk models were statistically the same but were different in the FY79-FY12 period. ARIMA 1 year forecasts and the status quo were not statistically different from the average futures contract models for the longer time period. Overall, the October futures contracts beat the status quo at each level of analysis except for the longer period. For both long term periods, the Random Walk 2 year forecast had the lowest chance of putting too little funding due to the difference in budgeted versus actual exchange rate.

V. Conclusion

This chapter reviews the research questions outlined in Chapter 1 and provides answers garnered from Chapter 4. Next, limitations in the data are explored as well as how to use the methodology in real world application. Future research naturally follows data limitations as the start of new avenues of inquiry. The chapter then summarizes the research.

Research Questions Revisited

The goal of the research is to provide a review of different forecasting methods as compared to the status quo. Specifically, this thesis examined each method in terms of variance or the deviation of the budgeted exchange rate from the actual exchange rate (as measured by the APE). After finding the mean of each method, further investigation revealed the use of the median as a more appropriate due to the skewed nature of the results. Using a bootstrap method, a 95% confidence interval was developed around each method's medians to see whether one method was statistically different from the other. Comparing these medians, the Air Force could use the Global Insight, futures contracts, forward rates, or a Random Walk model to replace the status quo method. Each method had a lower variance than the status quo and is statistically the same. Doing a longer term comparison, the Random Walk models, forward rates, and futures contracts are statistically significant and lower than the status quo from FY91 to FY12. For FY79 to FY12 the futures contracts and ARIMA 1 year forecasts are not statistically different from the status quo at 95% confidence, but are different at the 90% level. These results somewhat fit the literature. We would expect the Random Walk to perform as well as most methods, while Groshek and Felli experienced positive results with futures contracts and forward rates. The period from FY79 to FY12 was depressing in that the futures contracts broke were no long significantly different from the status quo. This research favors using an average of the October futures contract settlement prices as the budgeted rate.

Reviewing these methods in terms of simplicity is based on the method required to attain a budgeted exchange rate as well as the ability to explain the method's logic to the GAO, Inspector General, or an auditor. Upfront, Global Insight is the simplest method as it only requires using the 4th quarter's forecast of next year's annual rate. The most complicated is the ARIMA model as it requires either a computer program or knowledgeable technician to implement. The Random Walk models used the same computer program as the ARIMA models, but the Random Walk model could be implemented with a simple formula with an estimate for the error term ($Y_t = Y_{t-1} + \varepsilon_t$). The same could be said for the forward rate, but it also requires another data source for the interest rates. The futures data is a simple average of the settle prices, but the settle prices of various contracts expiring at different dates need combined (or "rolled" together) into a continuous series. Therefore, in terms of simplicity, the Global Insight method is the simplest to formulate.

The last research question focused on the probability of budgeting too little from Figure 1. As stated, a moderately lower rate is preferred so that the DoD will not have to take additional funding from the FCF account. This would lead to an overall lowering of the current FCF and reduce the opportunity cost of maintaining such a reserve. With that said, an ideal probability would be less than 50%. Over the short term, Global Insight was consistently under 50% across all three techniques while the Random Walk 2 year forecast was also under by 0.01%. Over the long term comparison, only the Random Walk 2 year and ARIMA 2 year forecasts managed to have a probability less than 50%. Since Global Insight has a lower median APE, and is simple to retrieve, the research supports this method in terms of the probability of having a higher budgeted rate than actual rate.

The research questions summarize to a variety of possible replacements to the status quo. In terms of variance, the futures contracts consistently provides lower medians than the status quo over the long term, but is not statistically different from the Global Insight methods in the short term. Global Insight is also the simplest method to explain, but may not have the academic literature background of the Random Walk, future contracts, and forward rate methods. Therefore it could be questionable to an auditor of the process, since the Air Force is using a rate without fully understanding how Global Insight calculates the rate (it would be a "black box" process). Finally, Global Insight consistently calculates a budgeted rate below the actual rate over the short term while the 2 year Random Walk forecast was consistent over the long term. This is preferable than a smaller budget requirement. This leads the research to recommend the average of futures contracts in October as the method to use in creating a budgeted rate. Formulating a budget rate via this method should give a 3.26% reduction to the median APE and avoid a $34.8 million opportunity cost (assuming the median APE holds for all currencies in the FY13 FCF account).

Data Limitations

Limitation in the data affected how we performed our analysis and the methods chosen. Each data set did not have all the currencies of interest over the required time periods. Global Insight data covered only the shorter period while the OECD interest rates for Japan only went back to 1989. Currency futures for other countries were available from the Chicago Mercantile Exchange (CME) Group although we did not have access to their historical data. The ideal data set would have each countries data (whether future contract prices, interest rates, or exchange rates) for the FY79 to FY14 timeframe. The OSD began publishing the adjusting rates in FY2000, and we could not use those adjusting rates to compare against each method. We therefore used the monthly average rate from the FRB H.10 report as the adjusting rates. The OSD adjusting rates and FRB H.10 monthly average do not give the exact same rate for each currency; however, they can be considered statistically the same in the median monthly rate (see Appendix F).

Future Research

The data for the futures contracts only contained three currencies and the contract were for next month, rather than for next year. The CME Group has additional currencies of interest to the DoD (such as the South Korean Won). Furthermore, CME Group data contains contracts with a variety of maturities to where an analyst could compare which contracts provide the lowest APE (e.g. using a contract with maturities at 3, 6, 9, or 12 months into the future, rather than one month). Funding, though, would be required to secure a subscription before the DoD would know if having the additional data would be economical.

Additional research into this area may focus on using more advanced forecasting techniques or the cost of changing fiscal law to allow risk mitigation techniques employed by private companies. Some research into forecasting exchange rates had success using artificial neural networks. Also, it would be interesting to see an application of the Kalman filter to exchange rate prediction. As for changing fiscal law, the ability to buy actual futures contracts does away with the need to forecast a currency rate. The DoD may have a higher exchange rate at the time of execution, but the budget would accurately reflect the requirement. The FCF could also be liquidated as the DoD would get the exact amount of currency required. Investigating the possible ramifications incurred by not allowing purchase of futures contracts would allow for a cost/benefit analysis.

Appendix F: Comparison of FRB H.10 and DoD Adjusting Rates

The FRB H.10 average monthly Pound and Yen exchange rates are not statistically different as their respective DoD adjusting rates. The exchange rates from both sources do not exhibit a normal distribution; therefore a nonparametric comparison was completed using the Wilcoxon method. The p-value of both pairs of currencies is extremely higher than 0.05, indicating the samples come from the same population (as shown by the top two pair comparisons below). This allows the use of the FRB H.10 data for method comparison in the long term analysis.

14. ABSTRACT
This thesis examines the current method of forecasting foreign currency exchange rates for the annual US Air Force budget. Using 5 methods against the status quo of a center-weighted average, the paper evaluates the absolute percent error (APE) over three time periods extending from Fiscal Year (FY) 1979 to FY 2014. The results strongly indicate that four of the alternative methods outperform over the short term, and one method for all three time periods. Furthermore, a non-parametric comparison of the median APE demonstrates statistical similarities between the four methods over the short term, and allows for the Air Force to choose which method to exercise for future forecasting. Overall, the paper recommends using a private firm's forecasts to decrease the median APE by 3.36% and avoiding $36.1 million opportunity cost.
